

DIAGNOSI ANATOMOPATOLOGICA ED ASPETTI MOLECOLARI

Dr. Luca Albarello

U.O. di Anatomia Patologica

Ospedale San Raffaele - Milano

Presezzo, 13/10/2018

**1) DIAGNOSI DI ISTOTIPO +
PARAMETRI PROGNOSTICI**

2) STADIAZIONE PATOLOGICA

3) PARAMETRI PREDITTIVI

Adenocarcinoma scarsamente differenziato del grosso intestino (rif. a) infiltrante il connettivo periviscerale.

Margini di resezione su pezzo chirurgico e margine radiale indenni da neoplasia.

Metastasi in 4 su 32 linfonodi periviscerali.

- Distanza minima dal margine di scollamento circonferenziale (margine radiale) (rif. g): 12 mm.
- Profondità di infiltrazione del connettivo periviscerale: 7 mm (rif. h).

Valutazione dell'espressione immunohistochimica delle proteine del sistema enzimatico MMR ("DNA Mismatch Repair", deputato alla correzione di appaiamenti scorretti delle basi nel DNA) su tessuto neoplastico.

- MSH2 (clone G219-1129): cellule carcinomatose con immunoreattività preservata;
- MLH1 (clone M1): cellule carcinomatose con immunoreattività non preservata;
- MSH6 (clone 44): cellule carcinomatose con immunoreattività preservata;
- PMS2 (clone EPR3947): cellule carcinomatose con immunoreattività non preservata.

Si osserva espressione di PD-L1 nel 20% della componente neoplastica.

(Valutazione dell'espressione di PD-L1 con anticorpo clone 22C3 su sezione istologica in paraffina; piattaforma Ventana):

Stadio TNM (rif. i): pT3(V1), pN2a, G3.

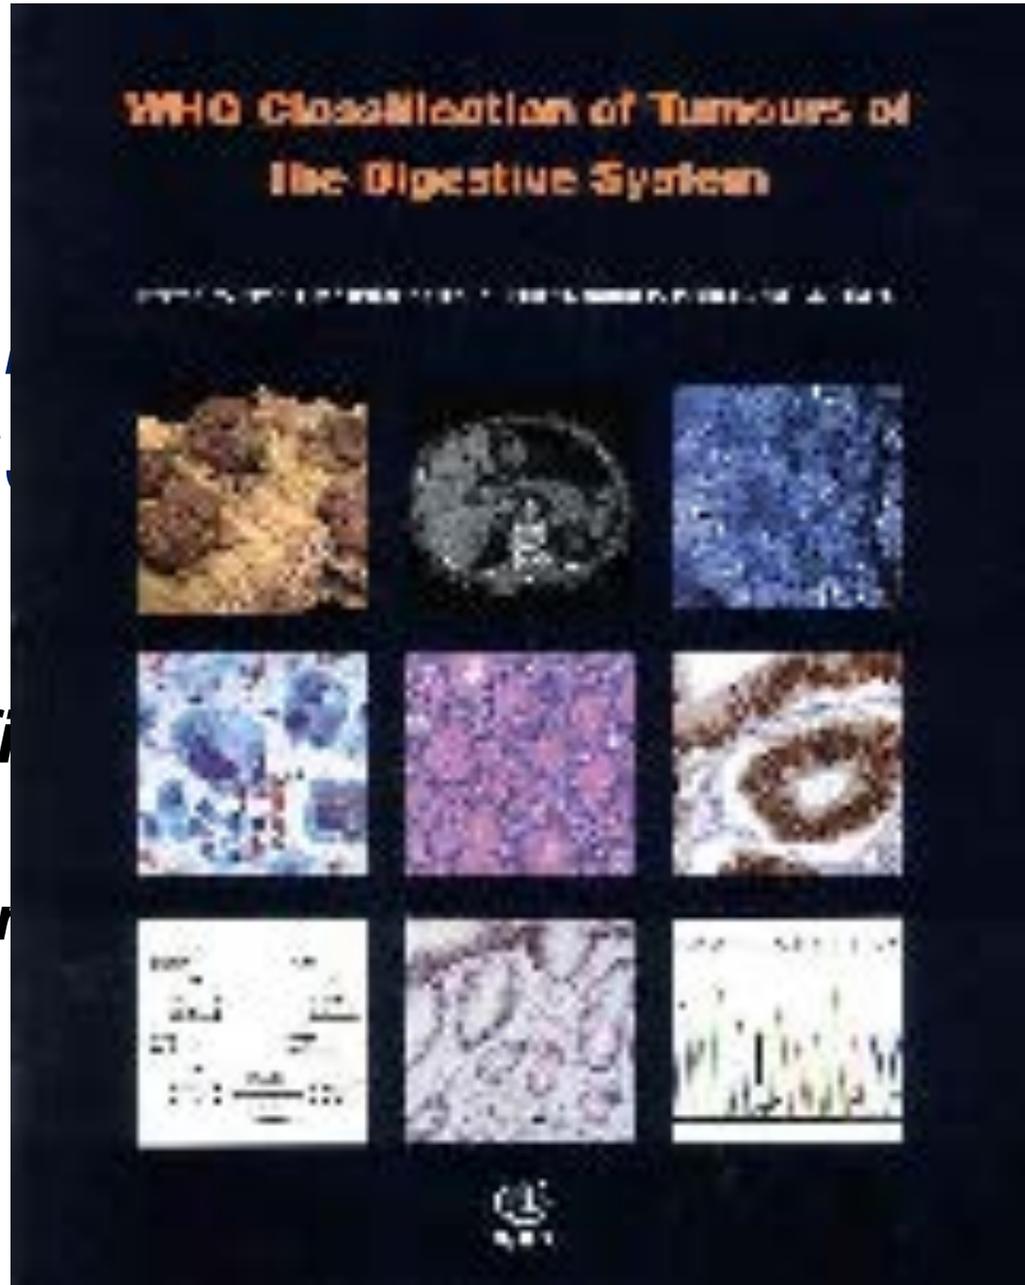

Riferimenti metodologici:

- (a) WHO Classification of Tumours. IARC 2010.
- (b) Valutazione espressa come: espansiva, infiltrativa (Jass, 1987).
- (c) Valutazione espressa come: assente, lieve, moderata, marcata (modificato da Jass, 1987).
- (d) Valutazione espressa come: assente, presente (Graham, 1990).
- (e) Score di riferimento: 0-9 foci/250x = basso grado; >=10 foci/250x = alto grado (Ueno, 2004).
- (f) Valutazione espressa come: osservata; non osservata.
- (g) Distanza misurata microscopicamente ed espressa in millimetri (Nagtegaal. Am J Surg Pathol, 2002).
- (h) Profondità misurata in mm (UICC, TNM Supplement, 4th edition, pag. 194).
- (i) UICC: TNM 8th Edition - 2017.

Tumor budding

Tumor budding – a histologic ‘snapshot’ of EMT

Tumor budding – *clinical significance*

Paper	Patients	Results
Ueno 2004 (<i>Gastro</i>)	292 Stage I	Independent prognostic factor
Ueno 2004 (<i>Ann Surg</i>)	638 Stage II & III	Independent prognostic factor
Wang 2005 (<i>Dis Colon</i>)	159 Stage I	10.1% pt with LN-mets
Park 2004 (<i>Dis Colon</i>)	109 Stage II & III	(1)61.5% had ITC (2)degree of TB correlated with ITC
Okuyama 2003 (<i>Dis Colon</i>)	196 Stage II	(1)43.3% of tumors showed budding (2)Significantly associated with LN mets (3)Independent prognostic factor
Tanaka 2003 (<i>Dis Colon</i>)	138 Stage II	Only budding associated with recurrence
Okuyama 2003 (<i>JSurg Onc</i>)	83 pT3	Lower overall survival (51.8% vs. 85%, P<0.002)
Shinto 2006 (<i>Dis Colon</i>)	136 Stage II & III	(1)Lymph node mets (P<0.0001) (2)High recurrence rate (P=0.0022)
Kajiwara 2010 (<i>Dis Colon</i>)	244 Stage II	Significant LN met risk
Homma 2010 (<i>JSurg Oncol</i>)	65 Stage II	Significant LN mets (P=0.002)

Tumor budding – *scoring systems*

Paper	n	Stain	Scoring system
Morodomi 1998 (<i>Cancer</i>)	40 CRC	H&E	Count performed at four locations (1.25mm² field area) and average calculated
Hase 1993 (<i>Dis Colon</i>)	663 CRC	H&E	N/A: classified according to subjective impression
Ueno 2002 (<i>Histopath.</i>)	638 CRC	H&E	10 or more buds in 25X field (0.385mm²)
Okuyama 2003 (<i>Dis Colon</i>)	196 CRC	H&E	N/A: classified according to subjective impression
Jass 2003 (<i>J Clin Path</i>)	95 CRC	H&E	5 buds in 40X field (area not specified)
Guzinska K 2005 (<i>Antican</i>)	24 CRC	H&E	Any budding considered positive
Ha 2005 (<i>Korean Can Ass</i>)	90 CRC	H&E	>7 buds in 20X field (area not specified)
Kanazawa 2008 (<i>Col Dis</i>)	159 CRC	H&E	0-1/3: mild; 1/3-2/3: moderate; >2/3: marked
Wang 2009 (<i>AJSP</i>)	128 CRC	H&E	5 fields (20X, 0.95mm²); a median count of 1 or more buds considered positive

Tumor budding in HSR

Ueno's criteria:

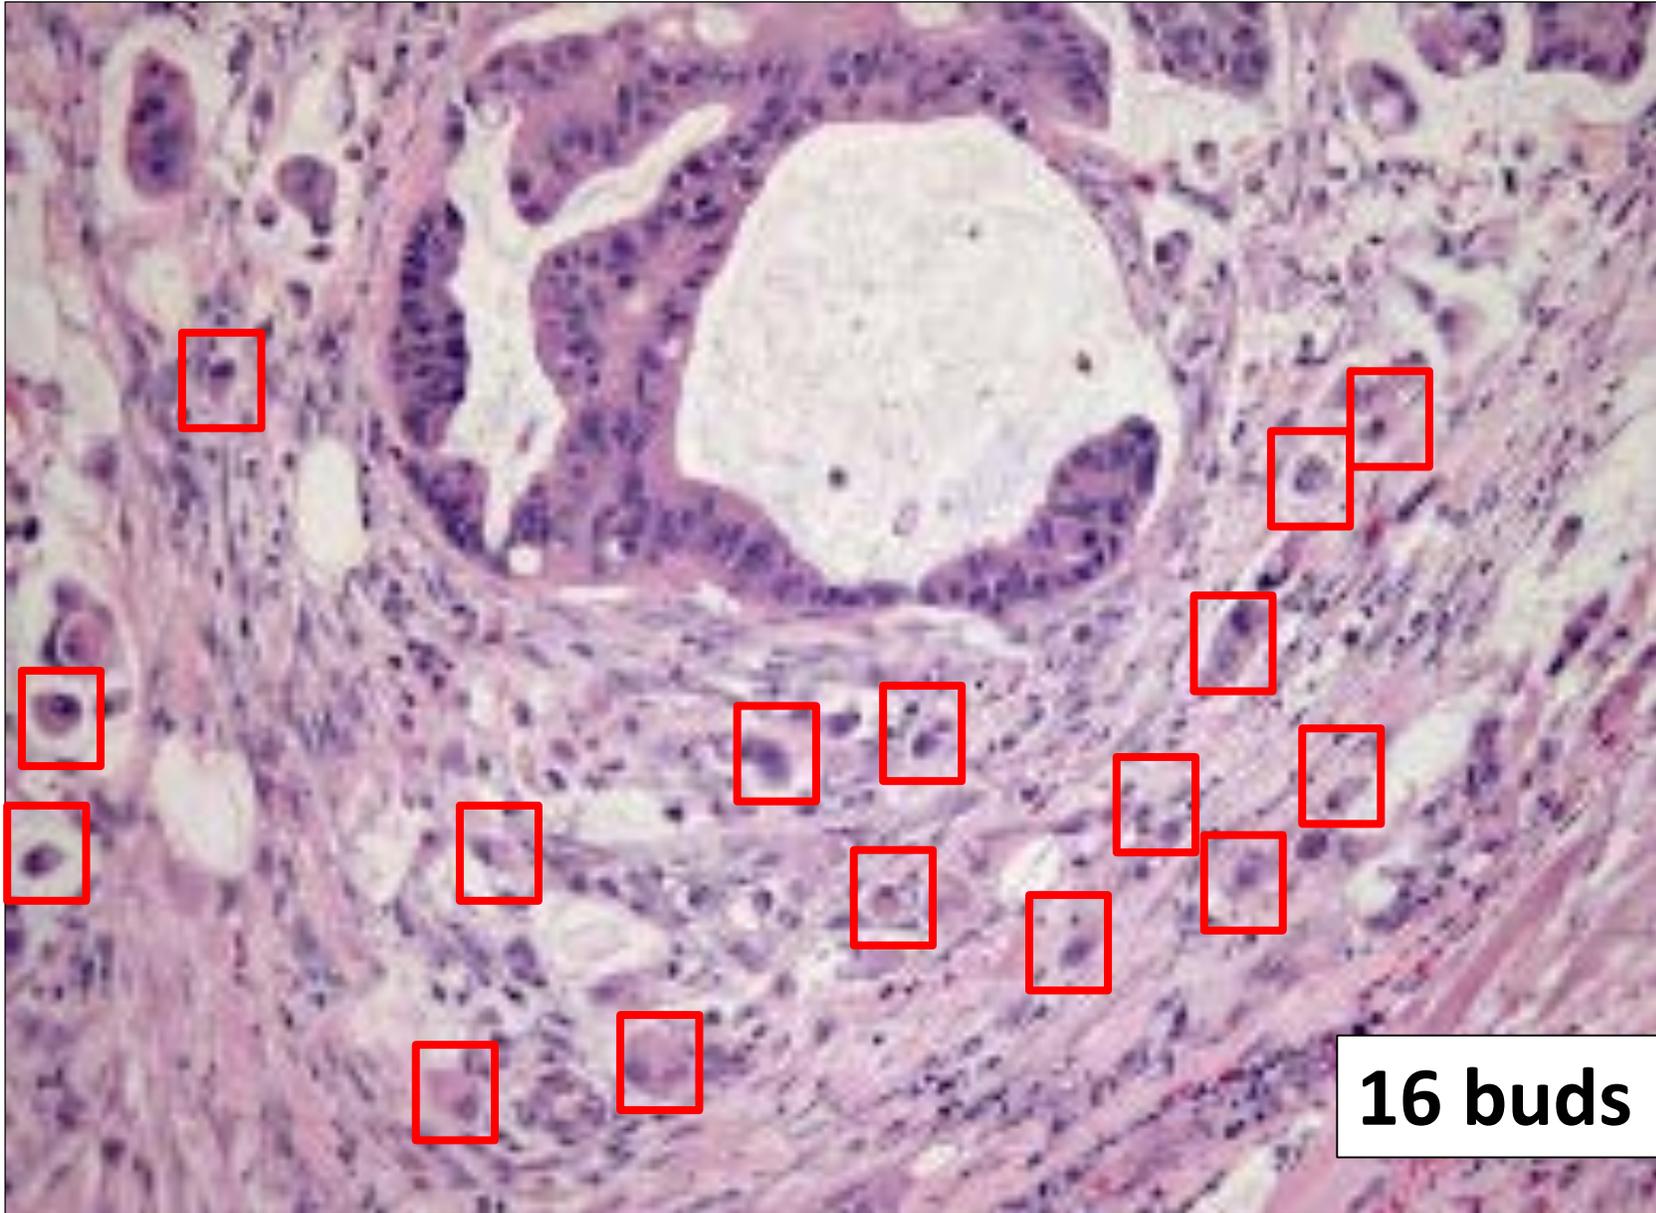

Tumor buds: 1-5 cells; 20x hpf (= 0.385 mm²)

Low grade budding: <5 buds in a 20x hpf

Borderline budding: 5-9 buds in a 20x hpf

High grade budding: >10 buds in a 20x hpf

Tumor budding

16 buds (20x)

Grado di regressione tumorale dopo terapia neoadiuvante (TRG)

- **TRG.** Nel caso di neoplasia sottoposta a chemio- e/o radioterapia neoadiuvante si applica un sistema di graduazione finalizzato a valutare la risposta alla terapia. Il grado di regressione tumorale (TRG, “Tumour Regression Grade”) è classificato con valori da 0 a 4 (Rödel e coll., Journal of Clinical Oncology, 2005, 34: 8688-8696).

Schematicamente:

- **grado “0”** = non si osserva regressione.
- **grado “1”** = scarsa regressione: prevale il tumore, la fibrosi costituisce meno del 26% della massa tumorale;
- **grado “2”** = moderata regressione: prevale il tumore, la fibrosi costituisce il 26-50% della massa tumorale;
- **grado “3”** = marcata regressione: prevale la regressione, la fibrosi costituisce più del 50% della massa tumorale;
- **grado “4”** = completa regressione: assenza di tumore.

GENOMIC INSTABILITY PATHWAYS: CIN, MSI, CIMP

The rate of mutations per nucleotide base pair is estimated to be as low as 10^{-9} per cellular generation.

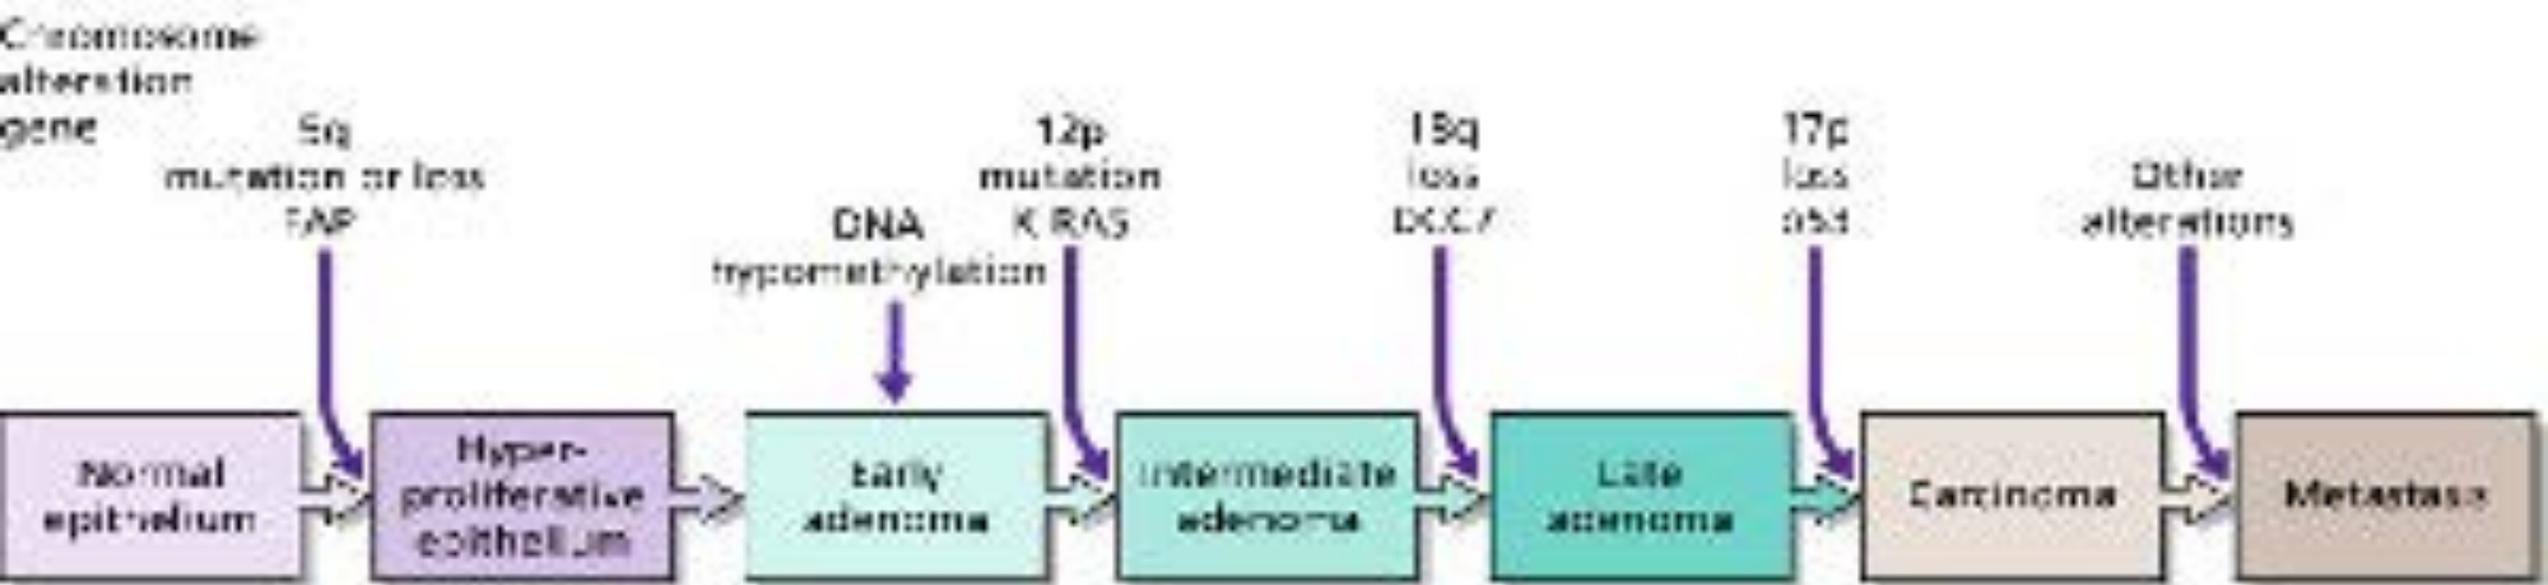

Cancer cells must acquire some form of intrinsic genomic instability, a “mutator phenotype”, that increases their rate of new mutations. Multiple genetic events → genomic instability → tumor progression.

In colon cancer, at least 3 distinct pathways of genomic instability have been described,

- chromosomal instability (**CIN**),
- microsatellite instability (**MSI**),
- CpG island methylator phenotype (**CIMP**).

MicroSatellite Instability

Microsatellite sequences (microsatellites) are repetitive DNA sequences usually several base pairs in length.

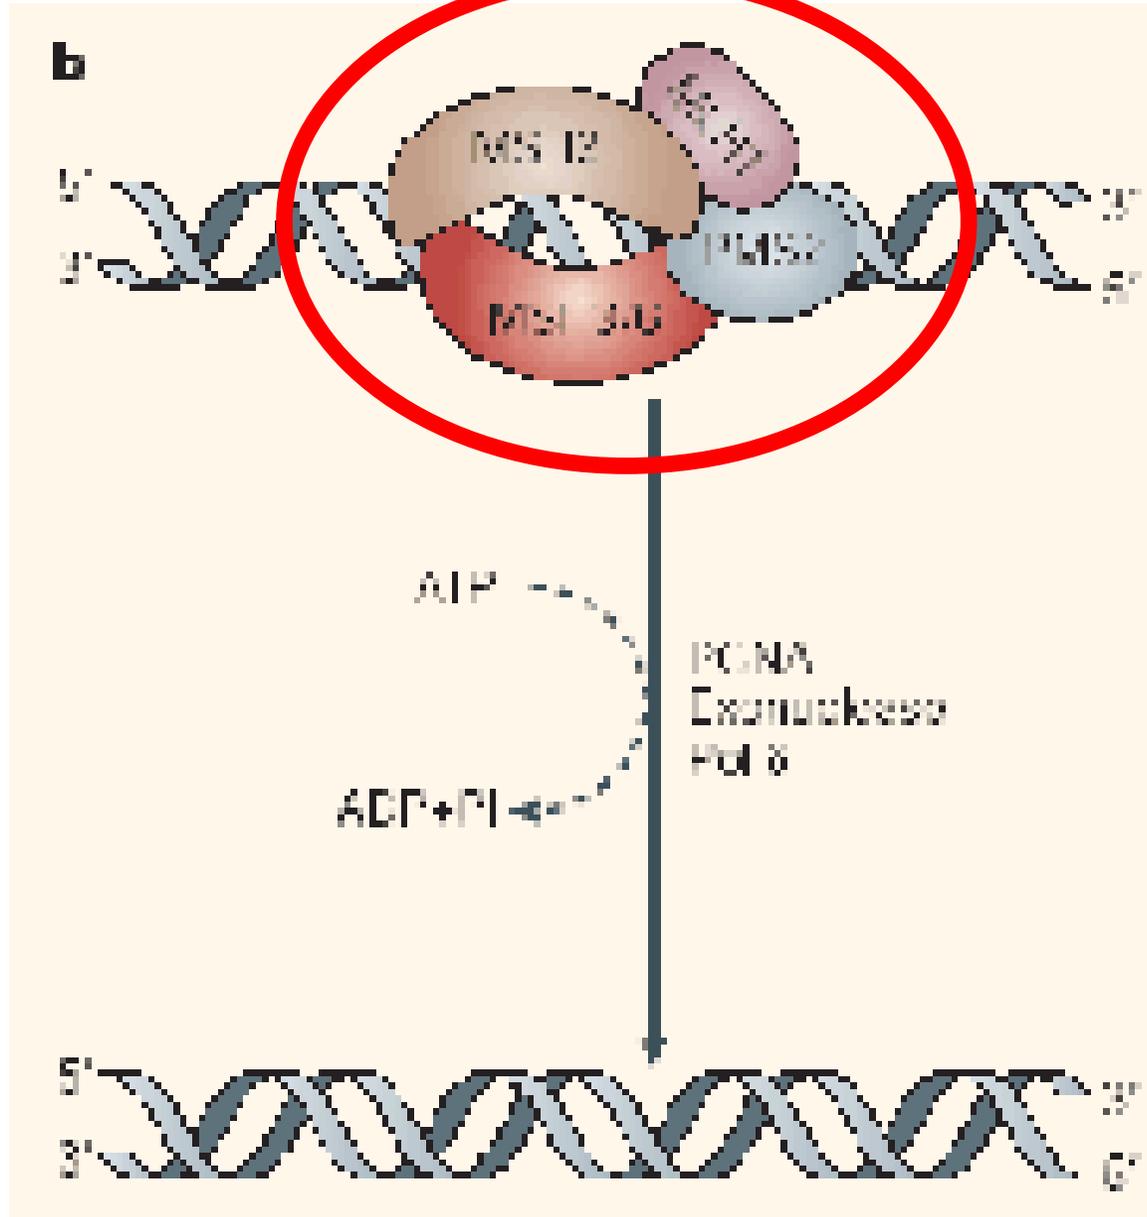

Microsatellite sequences are composed of non-coding DNA and are not parts of genes.

They are used as genetic markers to follow the inheritance of genes in families.

8 repeated sequences

DNA

**DNA Mismatch
Repair Machinery:**

Table 1. Cancers with an MSI-H frequency greater than 10%

Tumor type	Frequency, % (n)	Study
Colorectal cancer	13% (1066)	Hampel et al. (72)
Endometrial	22% (543) 33% (446)	Zigelboim et al. (73); Hampel et al. (74)
Gastric	22% (295)	TCEA (75)
Hepatocellular carcinoma	16% (37) ^a	Chappin et al. (76)
Ampullary carcinoma	10% (144)	Ruemmele et al. (77)
Thyroid	63% (30) ^a	Mitmaker et al. (78)
Skin (sebaceous tumors)	35% (20) ^a , 60% (25) ^a	Cesinaro et al. (79); Kruse et al. (80)
Skin (melanoma)	11% (58) ^a	Palmeri et al. (81)

^astudies of less than 100 patients.

Table 2. Cancers with an MSI-H frequency between 2% and 10%

Tumor type	Frequency, % (n)	Study
Ovarian	10% (1234)	Murphy and Wentzensen (52)
Cervical	8% (34) [#]	Lazo (83)
Esophageal adenocarcinoma	7% (76)	Faris et al. (84)
Soft-tissue sarcoma	5% (40)	Kawaguchi et al. (85)
Head and neck SCC	3% (53) [†]	Clavar et al. (86)
Renal cell carcinoma	2% (52)	Hammerschmidt et al. (87)
Ewing sarcoma	2% (55)	Aldinger et al. (88)

Abbreviation: SCC, squamous cell carcinoma.

[†]This number represents an aggregate of studies with different definitions of MSI-H, not all of which meet the Bethesda guidelines.

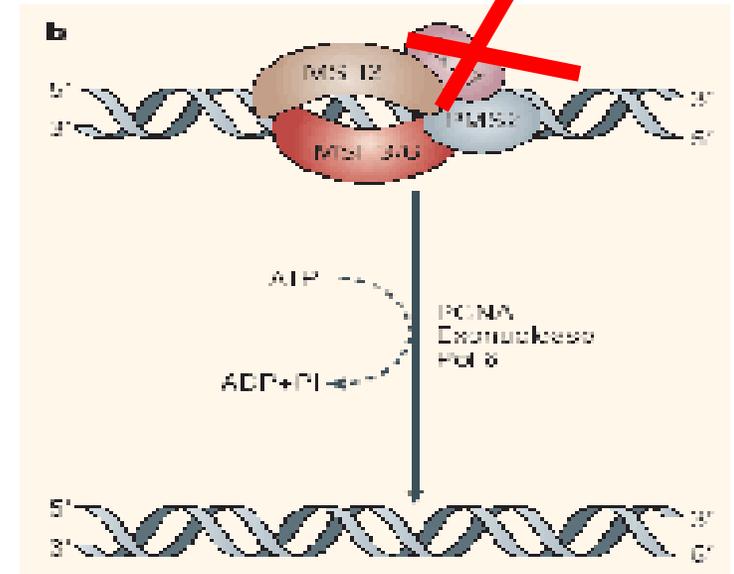

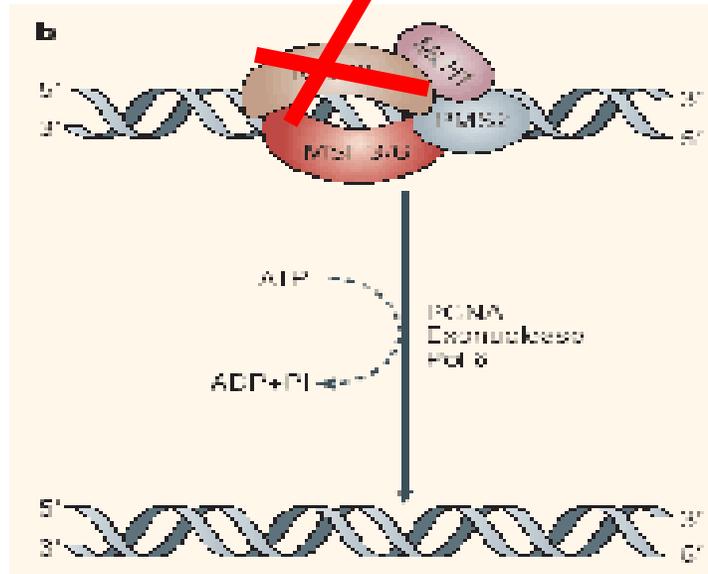

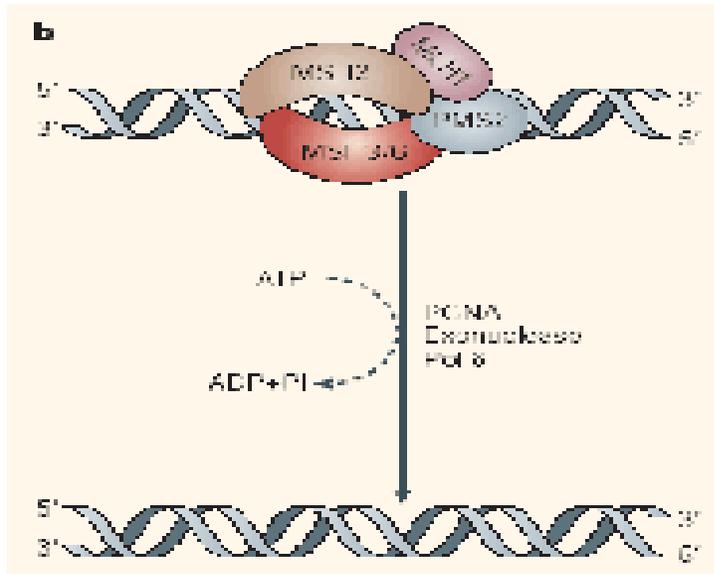

[#]MSI-H was defined as positivity in at least 2/8 markers.

MMR Immunohistochemistry

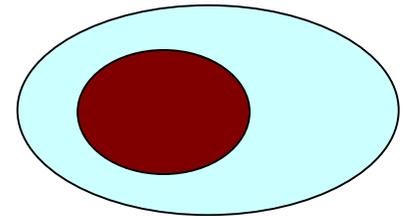

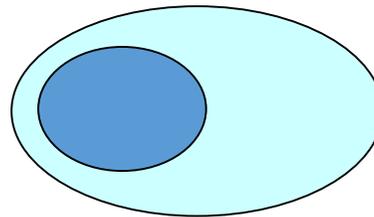

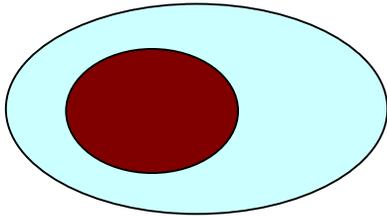

- Loss of expression of MMR proteins = reliable test of mismatch repair deficiency

(antibodies to *hMLH1*, *hMSH2*, *hMSH6* and *hPMS2*)

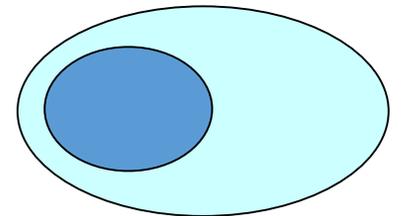

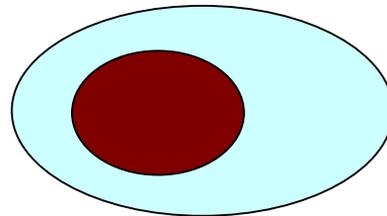

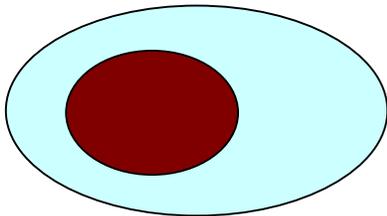

- This feature alone **can not** discriminate between **sporadic MSI-H** and **Lynch syndrome** due to the germ line mutation in *hMLH1* (approximately half of the cases).
- In the majority of sporadic MSI-H tumors there is characteristic *BRAF* (V600E) mutation not seen in Lynch syndrome.
- This provides for algorithmic approach to analysis of MSI-H tumors.

Hereditary colorectal cancer syndromes

<i>Syndrome</i>	<i>Preinvasive</i>	<i>CRC morphology</i>	<i>Extra colonic pathology</i>	<i>Mutation</i>
Lynch	Tubulo-villous adenoma, usually right-sided	Mucinous, medullary, signet ring and mixed types	Endometrial carcinoma; sebaceous skin tumors	MMR genes (<i>hMLH1</i> , <i>hMSH2</i> , <i>hMSH6</i> or <i>hPMS2</i>)
FAP	Tubular adenoma, microadenomas	Adenocarcinoma NOS	Fibromatoses, hepatoblastoma	<i>APC</i>
MAP	Tubular adenoma	Adenocarcinoma NOS	Duodenal carcinoma	<i>MUTYH</i>
PJS	Hamartomatous polyp with smooth muscle core	Adenocarcinoma NOS	Esophagus, Stomach, small intestine and pancreas carcinomas; sex cord tumors	<i>STK11</i>
JP	Hamartomatous polyp with dilated crypts	Not specified	Pancreatic, gastric duodenal carcinomas	<i>SMAD4/BMPR1A</i>
Cowden	Hamartomatous polyp	No increased risk for CRC	Breast, thyroid and uterus carcinomas	<i>PTEN</i>

○ Non-affected

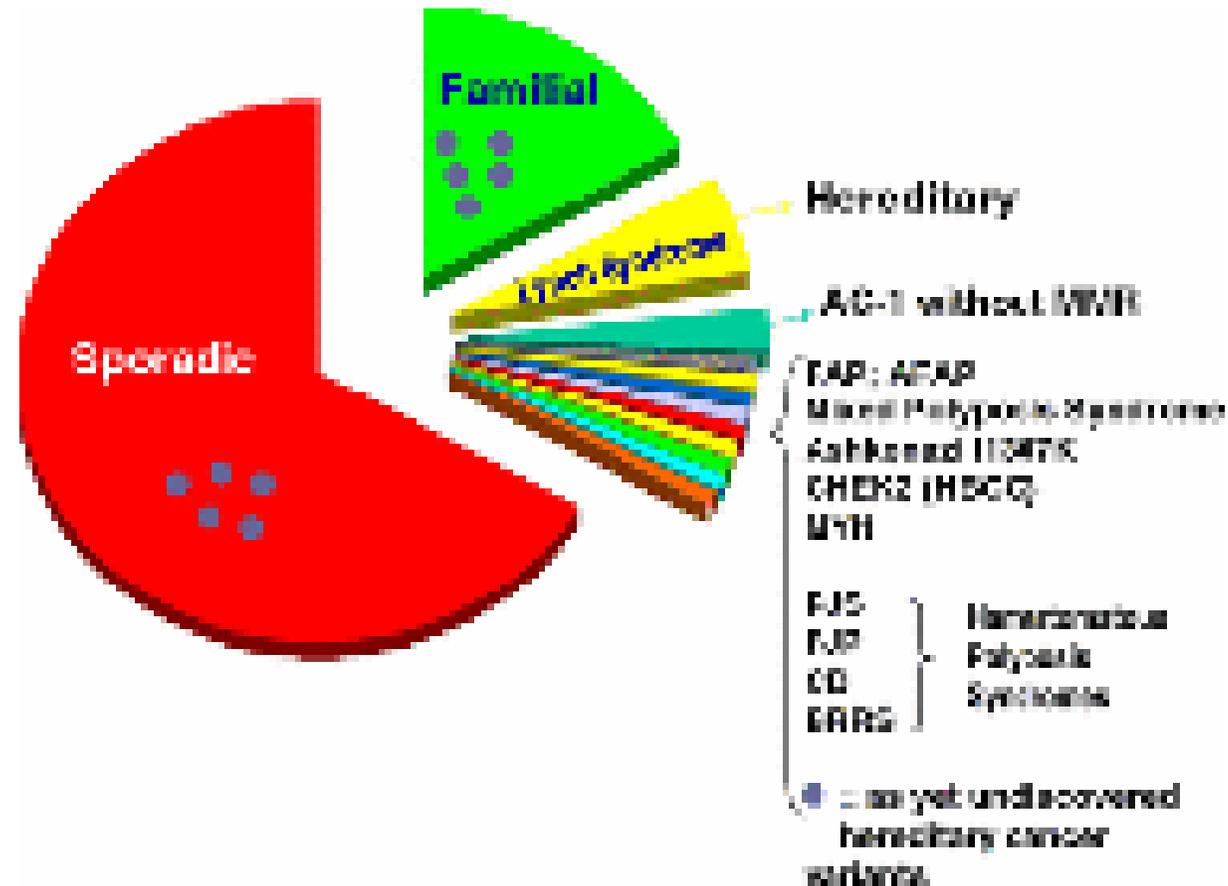

■ Affected with a mutation in the disease gene

◐ Affected with a mutation in the disease gene and carrier of HLA-B*27:01

◑ Affected with a mutation in the disease gene and carrier of HLA-B*57:01

▬ At risk

Circle graph depicting the marked genotypic and phenotypic heterogeneity in hereditary colorectal cancer syndromes. Note those with an increased risk for small bowel cancer (Revised with permission from Lynch et al (2004) Cancer 100:53–64.)

HNPCC (Lynch syndrome)

Cardinal Features

CRC in HNPCC

- **poorly differentiated,**
 - **mucoïd and signet-cell features,**
 - **Crohn' s-like reaction,**
 - **excess of tumor infiltrating lymphocytes (TILs)**
 - **MSI-H**
- Increased survival from CRC, when controlled for age and stage;
 - Accelerated carcinogenesis and reduced interval CRC (adenoma-ca within 2–3 years, as opposed to 8–10 years in the general population)
 - Sebaceous adenomas, sebaceous carcinomas, and multiple keratoacanthomas in the Muir–Torre syndrome variant of Lynch syndrome;
 - The *sine qua non*, the identification of a germline MMR mutation segregating with syndrome-affected individuals in the family.

MSI testing

HNPCC

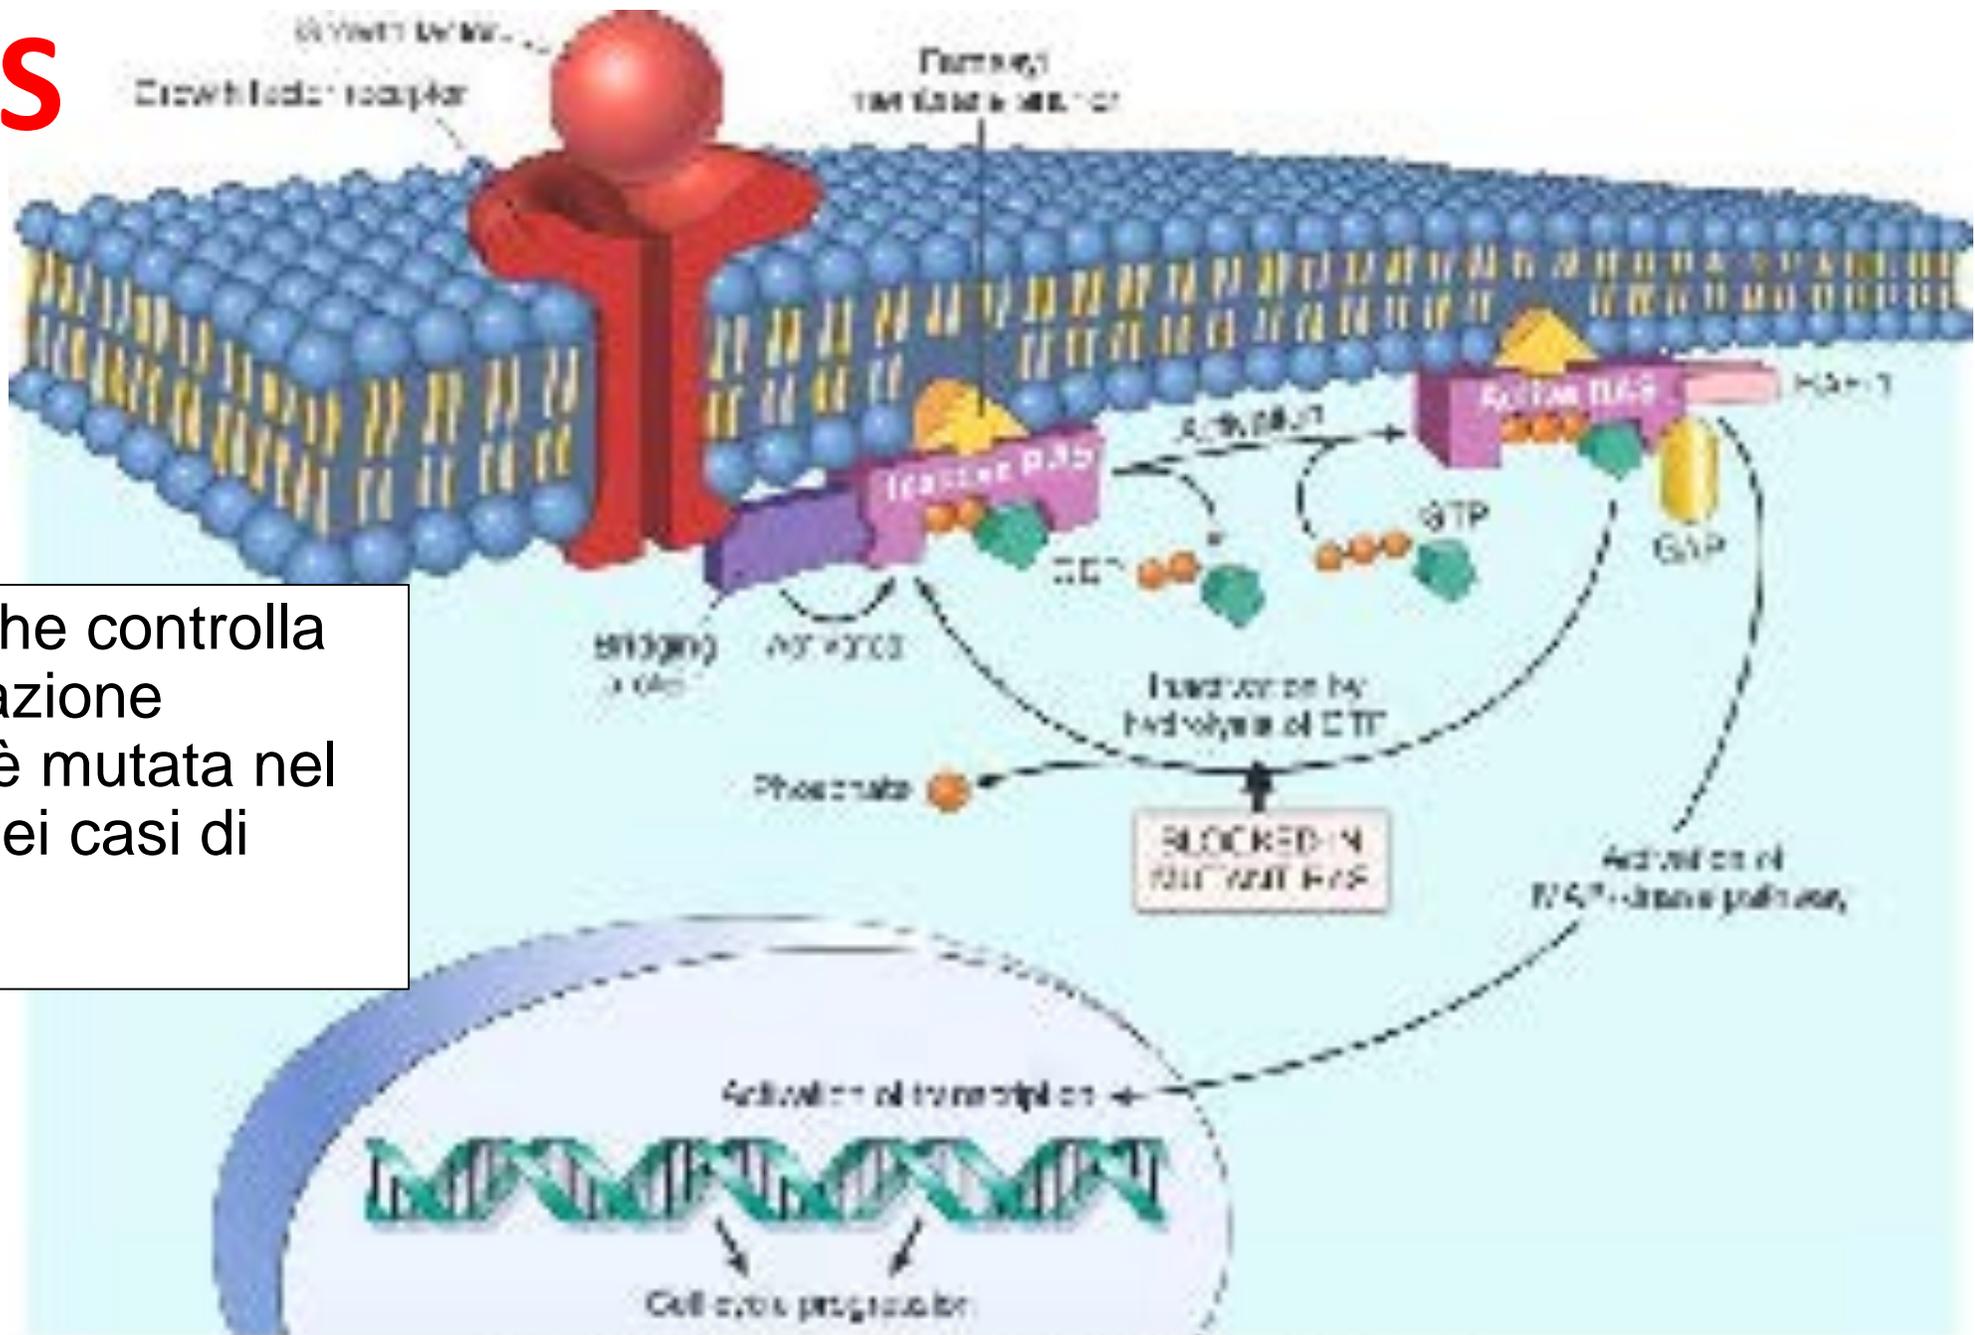

Since **MSI-H** cancers have a favorable prognosis, MSI testing for stage II cases can help in making decisions regarding adjuvant chemotherapy.

(J Clin Oncol. 2010;28(20):3219-3226.)

Since **MSI-H** cancers do not respond well to 5-FU therapy, MSI status is also important in determining the choice of chemotherapeutic regimen.

(J Clin Oncol. 2010;28(20):3219-3226.)

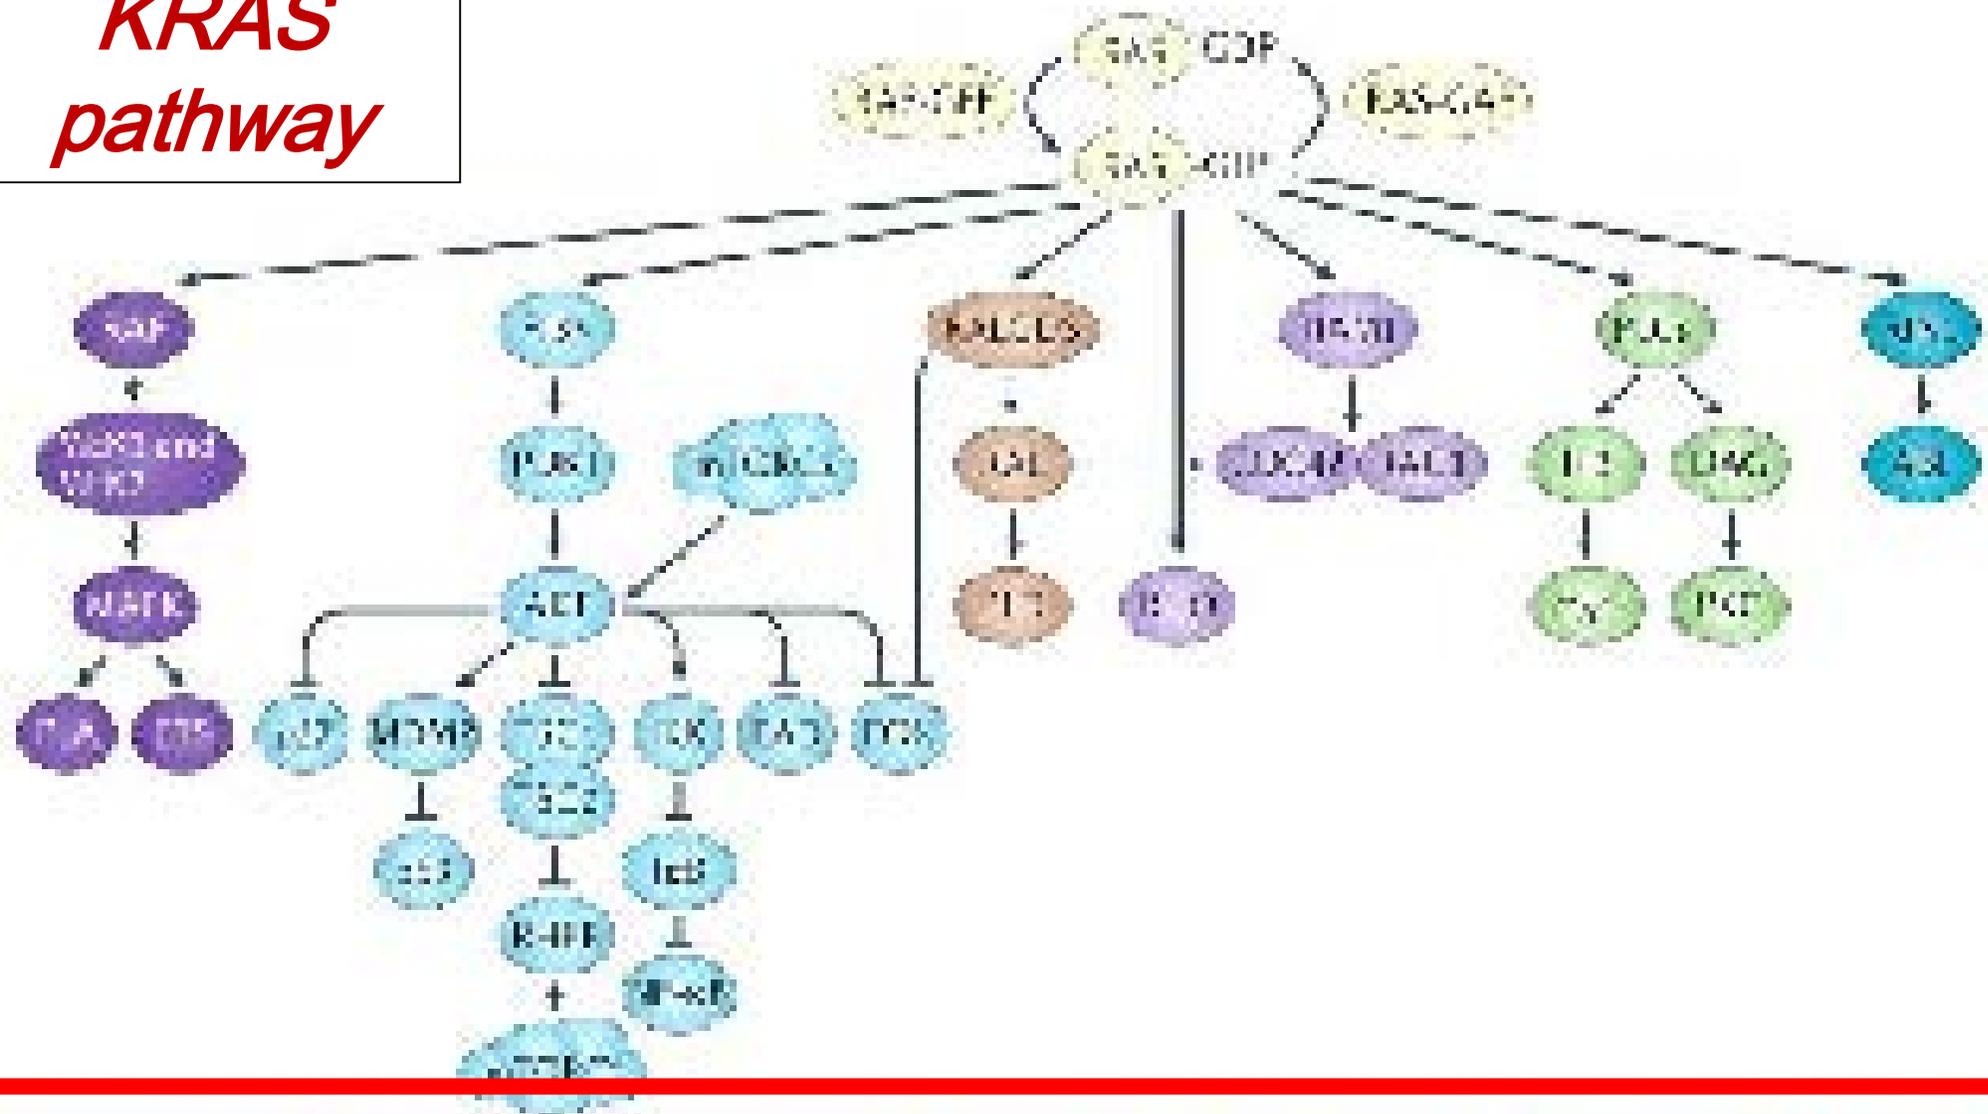

KRAS

GTP-asi che controlla la proliferazione cellulare, è mutata nel 50-60% dei casi di CRC.

Diagram illustrating the KRAS signaling pathway. A Growth factor receptor (red) is embedded in a cell membrane (blue lipid bilayer). Upon binding of a Growth factor (red sphere), the receptor dimerizes and activates. This leads to the recruitment of Ras p35 (purple) and the exchange of GDP for GTP (orange spheres). Activated Ras p35 then activates Raf-1 (pink), which in turn activates MEK1-driven pathway (green), leading to the activation of transcription and cell cycle progression. A mutation in KRAS is shown as a 'BLOCKED IN MUTANT KRAS' (pink box), where the hydrolysis of GTP to GDP is inhibited, leading to a 'Phosphate' (orange sphere) being released. This results in a 'BLOCKED IN MUTANT KRAS' state, which prevents the activation of the MEK1-driven pathway and thus inhibits transcription and cell cycle progression.

CpG islands

- «**CpG** sites» are regions of DNA where a cytosine nucleotide occurs next to a guanine nucleotide in the linear sequence of bases along its length.
- “CpG” is shorthand for “-C-phosphate-G-”, that is C and G separated by only one phosphate; phosphate links any two nucleosides together in DNA.
- CpG islands are genomic regions containing high conc. of CpG sites.
- In mammalian genomes CpG islands are 300-3000 bp in length, and are found in or near approx 40% of promoters of mammalian genes.
- About 70% of human promoters have a high CpG content.

“Molecular-pathological” classification of colorectal carcinoma (2009)

	Chromosomal instability pathway	Mismatch repair pathway	Serrated pathway		Hybrid pathway
Heridity	Hereditary and sporadic (FAP, MUTYH)	Hereditary (HNPCC)	Hereditary and sporadic		Sporadic
CIMP status	Negative	Negative	CIMP-High	CIMP-High	CIMP-Low
MSI status	MSS	MSI-H	MSI-H	MSI-L / MSS	MSI-L or MSS
Chromosomal instability	Present	Absent	Absent	Absent	Present
KRAS mutation	+++	+/-	---	---	+++
BRAF mutation	---	---	+++	+++	---
MLH1 status	Normal	Mutation	Methylated	Partial methylation	Normal
MGMT methylation	---	---	+/-	+++	+++
Precursor lesion			SSA/P	TSA	
Side		RIGHT colon	RIGHT colon	LEFT colon	

Abbreviations: CIMP, CpG island methylator phenotype; MGMT, O-6-methylguanine DNA methyltransferase; MSI, microsatellite instability; MSI-H, high-level microsatellite instability; MSI-L, low-level microsatellite instability; MSS, microsatellite stability.

νόμος

"Intramucosal"—infiltration of tumour in the lamina propria and confined to the mucous membrane (above the muscularis mucosae). This term is not synonymous with carcinoma in situ. Intramucosal carcinoma of the stomach can metastasize to regional lymph nodes.

Fixed submucosal and signifying for carcinoma in situ, lesions of the stomach should be considered forms of intramucosal carcinoma.

"Superficial spreading carcinoma": extensive lateral spread of the tumour, primarily in the mucosa and superficial submucosa. It is synonymous with diffuse gastric carcinoma.

Carcinoma in situ, in the stomach, is an expression applied by some to mucosal lesions including adenomas, in which the epithelial cells show conspicuous changes described as severe dysplasia or dysplasia. The term should not be used if there is invasion of cells across the basement membrane of the glands (see intramucosal carcinoma, above).

Stomach, WHO 1976

νόμος

Superficial spreading carcinoma: extensive lateral spread of the tumour, primarily in the mucosa and superficial submucosa. It is not synonymous with intramucosal carcinoma.

Carcinoma in situ: adenocarcinoma which has not invaded the lamina propria (Sect. 8). This diagnosis may be difficult or impossible to make with certainty especially on endoscopic biopsy.

Intramucosal carcinoma: carcinoma has spread within the lamina propria but not beyond the muscularis mucosae. Lymph node metastasis is found in about 2%–3% of the cases.

νόμος

Large intestine Epithelial tumours

Adenomas can show foci of disorderly glandular proliferation together with severe cellular atypia. Such changes, without invasion of the lamina propria, have been described as non-invasive carcinoma or carcinoma-in-situ. Invasive carcinoma in an intestinal adenoma should be diagnosed only when the tumour has traversed the muscularis mucosae (Fig. 19-61). The reason for this is that metastasis does not occur unless the submucosa is invaded.

WHO 1976

τάξις

1989

νόμος

Large intestine - Epithelial tumours

It is not unusual to see several grades of dysplasia within one adenoma. The diagnostic grade is based on the most severely dysplastic area. When there is invasion by neoplastic epithelium into the lamina propria but no penetration beyond the muscularis mucosae, the descriptive term 'intramucosal carcinoma' is, strictly speaking, correct. However, intramucosal carcinoma of the colon has not been shown to metastasize, and for this reason 'carcinoma in situ' is more appropriate. Invasive carcinoma should only be reported when spread through the muscularis mucosae into the submucosa has been demonstrated. To prevent potential confusion, the term 'intramucosal carcinoma' is best avoided in the large bowel. The term 'in situ carcinoma' should likewise be avoided since it does not indicate whether invasion into the submucosa has occurred.

WHO 1989

		Type of response	
		Agreement (n = 200/100%)	Disagreement
Western description	Adenoma	0	0
	Colorectal adenocarcinoma	0	0
		0	0

Background

Large discrepancies between Western and Japanese pathologists have been found in the diagnosis of adenoma/dysplasia versus carcinoma for gastric and colorectal glandular lesions and for oesophageal squamous lesions. These differences in diagnostic criteria have caused considerable problems in the interpretation of Japanese cancer research by Western clinicians and researchers, and vice versa. These discrepancies therefore called for a united effort to reach a consensus on the nomenclature of gastrointestinal epithelial neoplastic lesions.

Esigenza di utilizzare una terminologia omogenea per stomaco e grosso intestino, per rendere più semplice la comunicazione tra produttori e fruitori di diagnosi:

- 1) rendere univoci i termini
- 2) rendere univoci i concetti significati dai termini
- 3) Produrre una classificazione «universalmente accettata»

- **Aprile 1998** → Consensus Meeting in Padova (solo x stomaco!)
- **Settembre 1998** → World Congress in Gastroenterology in Vienna
- **2000** → “The Vienna classification of gastrointestinal epithelial neoplasia.”

Histopathology

The defining feature of colorectal adenocarcinoma is invasion through the muscularis mucosae into the submucosa.

Lesions with the morphological characteristics of adenocarcinoma that are confined to the epithelium of the colonic mucosa and lack invasion through the muscularis mucosae into the submucosa have virtually no risk of metastasis. Therefore, high-grade intra-

epithelial neoplasia is a more appropriate term than 'adenocarcinoma in situ', and 'intramucosal' neoplasia is more appropriate than 'intramucosal adenocarcinoma'. Use of these proposed terms helps to avoid overtreatment.

2000

Large intestine epithelial neoplasms: synopsis of terms

A.D. 2011

Equator and Four Winds (© 2011) Ltd. 2011

“... Colonic intramucosal carcinoma behaves like a benign adenoma and for this reason polyps harbouring “in situ” or “intramucosal” cancer (Categories 4.2 and 4.4, respectively) are not generally regarded as “malignant” polyps and classified as high grade dysplasia, high grade intraepithelial neoplasia or mucosal high grade neoplasia”.

A.D. 2012

European guidelines for quality assurance in colorectal cancer screening and diagnosis. First Edition
Anatomical sites of colorectal lesions

© 2012 European Society of Gastrointestinal Endoscopy (ESGE)
© 2012 European Society of Gastroenterology and Digestive Endoscopy (ESGE)

The WHO definition of adenocarcinoma in use when the EU Guidelines were developed excluded diagnosis of intramucosal carcinoma in the colon or rectum, in contrast to the accepted WHO definitions for the stomach, oesophagus and small bowel. In the latter cases, a decision on surgical vs. local therapy is made based on respective protocols. Comparable lesions in the colon and rectum are reported as high-grade mucosal neoplasia because a carcinoma in the colon is defined by infiltration of the submucosa according to the WHO classification.

malignancy. The diagnosis of colorectal cancer on biopsy, clearly depends on definition. In Japan and elsewhere in Asia it is largely a cytological diagnosis whilst in the US and some areas of Europe, architectural features are emphasised. In the UK we follow European and TNM criteria that requires definitive evidence of submucosal spread to make a diagnosis of adenocarcinoma and does not allow the diagnosis of intramucosal adenocarcinoma.^{7, 18} The latter term, and plus, are not encouraged in the lower gastrointestinal tract, to avoid over-treatment, of lesions considered to have negligible risk of metastatic spread. The term 'high-grade dysplasia' should be used to encompass these.

Biop

“... The requirement to demonstrate submucosal invasion undoubtedly creates diagnostic difficulties because **biopsies may not show submucosal tissue**. Biopsies from colorectal tumours therefore often fail to overtly demonstrate submucosal invasion. However, the presence of a **desmoplastic stromal response** to neoplastic glands is **usually considered acceptable** for a diagnosis of adenocarcinoma, as this is a rare finding in ‘intramucosal adenocarcinoma’. Caution should be exercised with polyps or polypoid lesions, as a desmoplastic stroma might be encountered in these without submucosal invasion, related to surface ulceration and/or previous biopsy. “

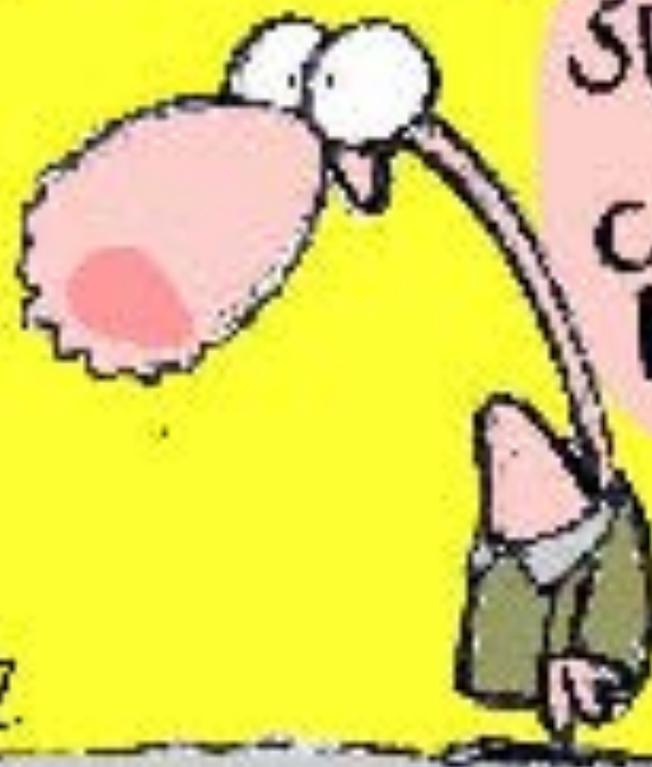

“... Although **not yet proven** in definitive studies, we believe that juxtaposition of neoplastic glands to structures known to be in the submucosa, such as neural structures, fat and larger blood vessels, particularly arterioles and venules, are of considerable help in making a diagnosis of invasive adenocarcinoma. “

Affected with a mutation on chromosome belonging to HLA-B*27:2 specificity

At risk

Circle graph depicting the marked genotypic and phenotypic heterogeneity in hereditary colorectal cancer syndromes. Note those with an increased risk for small bowel cancer (Revised with permission from Lynch et al (2004) Cancer 100:53–64.)

HNPCC (Lynch syndrome)

Cardinal Features

CRC in HNPCC

- **poorly differentiated,**
 - **mucoïd and signet-cell features,**
 - **Crohn' s-like reaction,**
 - **excess of tumor infiltrating lymphocytes (TILs)**
 - **MSI-H**
- Increased survival from CRC, when controlled for age and stage;
 - Accelerated carcinogenesis and reduced interval CRC (adenoma-ca within 2–3 years, as opposed to 8–10 years in the general population)
 - Sebaceous adenomas, sebaceous carcinomas, and multiple keratoacanthomas in the Muir–Torre syndrome variant of Lynch syndrome;
 - The *sine qua non*, the identification of a germline MMR mutation segregating with syndrome-affected individuals in the family.

Pathology of the hereditary colorectal carcinoma

- Approximately 150,000 new patients with colorectal carcinomas (CRC) are diagnosed in the United States each year (8.5% of all new cancers [1]).
- 30% of patients will have a positive familial history with first or second degree relative affected by cancer [2].
- Small proportion of such families have mutations in one of the currently identified susceptibility genes.
- Several autosomal dominant syndromes may have sufficiently characteristic pathologic presentation allowing their recognition even in the absence of relevant clinical information:
 - Lynch syndrome
 - Familial Adenomatous Polyposis (FAP)
 - Attenuated FAP
 - Juvenile polyposis
 - Cowden syndrome
 - Peutz Jeghers syndrome
 - Hereditary mixed polyposis syndrome (HMPS)

- Burgart LJ (2005) Testing for defective mismatch repair in colorectal carcinoma. A practical guide. Arch Pathol Lab Med 129:1385–138

Lynch syndrome (HNPCC)

- **The most common of the heritable colon cancer syndromes**
- **Autosomal dominant**
- **Germline mutations in mismatch repair (MMR) genes**
- **Lack of MMR proteins leads to genomic instability (high frequency microsatellite instability, MSI-H)**
- **Development of various cancers**
- **3–5% of the total colon cancer in the United States**

- Lynch syndrome (HNPCC): complex clinical presentation (syndrome), multiple colonic polyps + defining genetic abnormality (mutation in one of the MMR genes)
- “Familial colorectal cancer type-X” or “Familial CRC of undetermined type” should be used for familial occurrence of colorectal carcinoma in which no mutation in MMR genes or other genes known to predispose to CRC were found

Amsterdam Criteria I and II (International Collaborative Group) for the Diagnosis of HNPCC

Amsterdam Criteria I

1. Three or more relatives with histologically verified colorectal cancer, one of whom is a first-degree relative of the other two; FAP should be excluded
2. Colorectal cancer involving at least two generations
3. One or more colorectal cancer cases diagnosed before the age of 50

Amsterdam Criteria II

1. Three or more relatives with histologically verified HNPCC-associated cancer (colorectal cancer, cancer of the endometrium, small bowel, ureter, or renal pelvis), one of whom is a first-degree relative of the other two; FAP should be excluded
2. Colorectal cancer involving at least two generations
3. One or more cancer cases diagnosed before the age of 50

Amsterdam Criteria II

1. Three or more relatives with histologically verified HNPCC-associated cancer (colorectal cancer, cancer of the endometrium, small bowel, ureter, or renal pelvis), one of whom is a first-degree relative of the other two; FAP should be excluded
2. Colorectal cancer involving at least two generations
3. One or more cancer cases diagnosed before the age of 50

Bethesda Criteria for Testing Colorectal Tumors for MSI

1. Individuals with cancer in families that meet the Amsterdam criteria
2. Individuals with two HNPCC-related cancers, including synchronous and metachronous colorectal cancers or associated extracolonic cancers*
3. Individuals with colorectal cancer and a first-degree relative with colorectal cancer and/or HNPCC-related extracolonic cancer and/or a colorectal adenoma; one of the cancers diagnosed at age < 45 years,[†] and the adenoma diagnosed at age < 40 years
4. Individuals with colorectal cancer or endometrial cancer diagnosed at age < 45 years[†]
5. Individuals with right-sided colorectal cancer with an undifferentiated pattern (solid/cribriform) on histology diagnosed at age < 45 years^{†‡}
6. Individuals with signet-ring cell-type colorectal cancer diagnosed at age < 45 years^{† §}
7. Individuals with adenomas diagnosed at age < 40 years

Abbreviations: MSI, microsatellite instability; HNPCC, hereditary nonpolyposis colorectal cancer; AGA, American Gastroenterological Association.

- Endometrial, ovarian, gastric, hepatobiliary, small bowel, or transitional cell carcinoma of the renal pelvis or ureter.
- [†] Guidelines for age of cancer diagnosis have been adapted to <50 years in the AGA Medical Position Statement (Bethesda criteria modified).
- [‡] Solid/cribriform defined as poorly differentiated or undifferentiated carcinoma composed of irregular, solid sheets of large eosinophilic cells and containing small gland-like spaces.
- [§] Composed of >50% signet ring cells.

Revised Bethesda guidelines for MSI testing

Who should be tested for MSI:

- 1. Colorectal cancer diagnosed in a patient who is less than 50 yr of age**
- 2. Presence of synchronous, metachronous colorectal, or other Lynch syndrome-associated tumors (colorectal, endometrial, stomach, ovarian, pancreas, ureter and renal pelvis, biliary tract, small bowel, brain, and sebaceous gland adenomas and keratoacanthomas), regardless of age**
- 3. Colorectal cancer with the MSI-H histology (presence of tumor infiltrating lymphocytes, Crohn's-like lymphocytic reaction, mucinous/signet-ring differentiation, or medullary growth pattern) diagnosed in a patient who is less than 60 yr of age**
- 4. Colorectal cancer diagnosed in one or more first-degree relatives with an HNPCC-related tumor, with one of the cancers being diagnosed under age 50 yr**
- 5. Colorectal cancer diagnosed in two or more first- or second-degree relatives with HNPCC-related tumors, regardless of age**

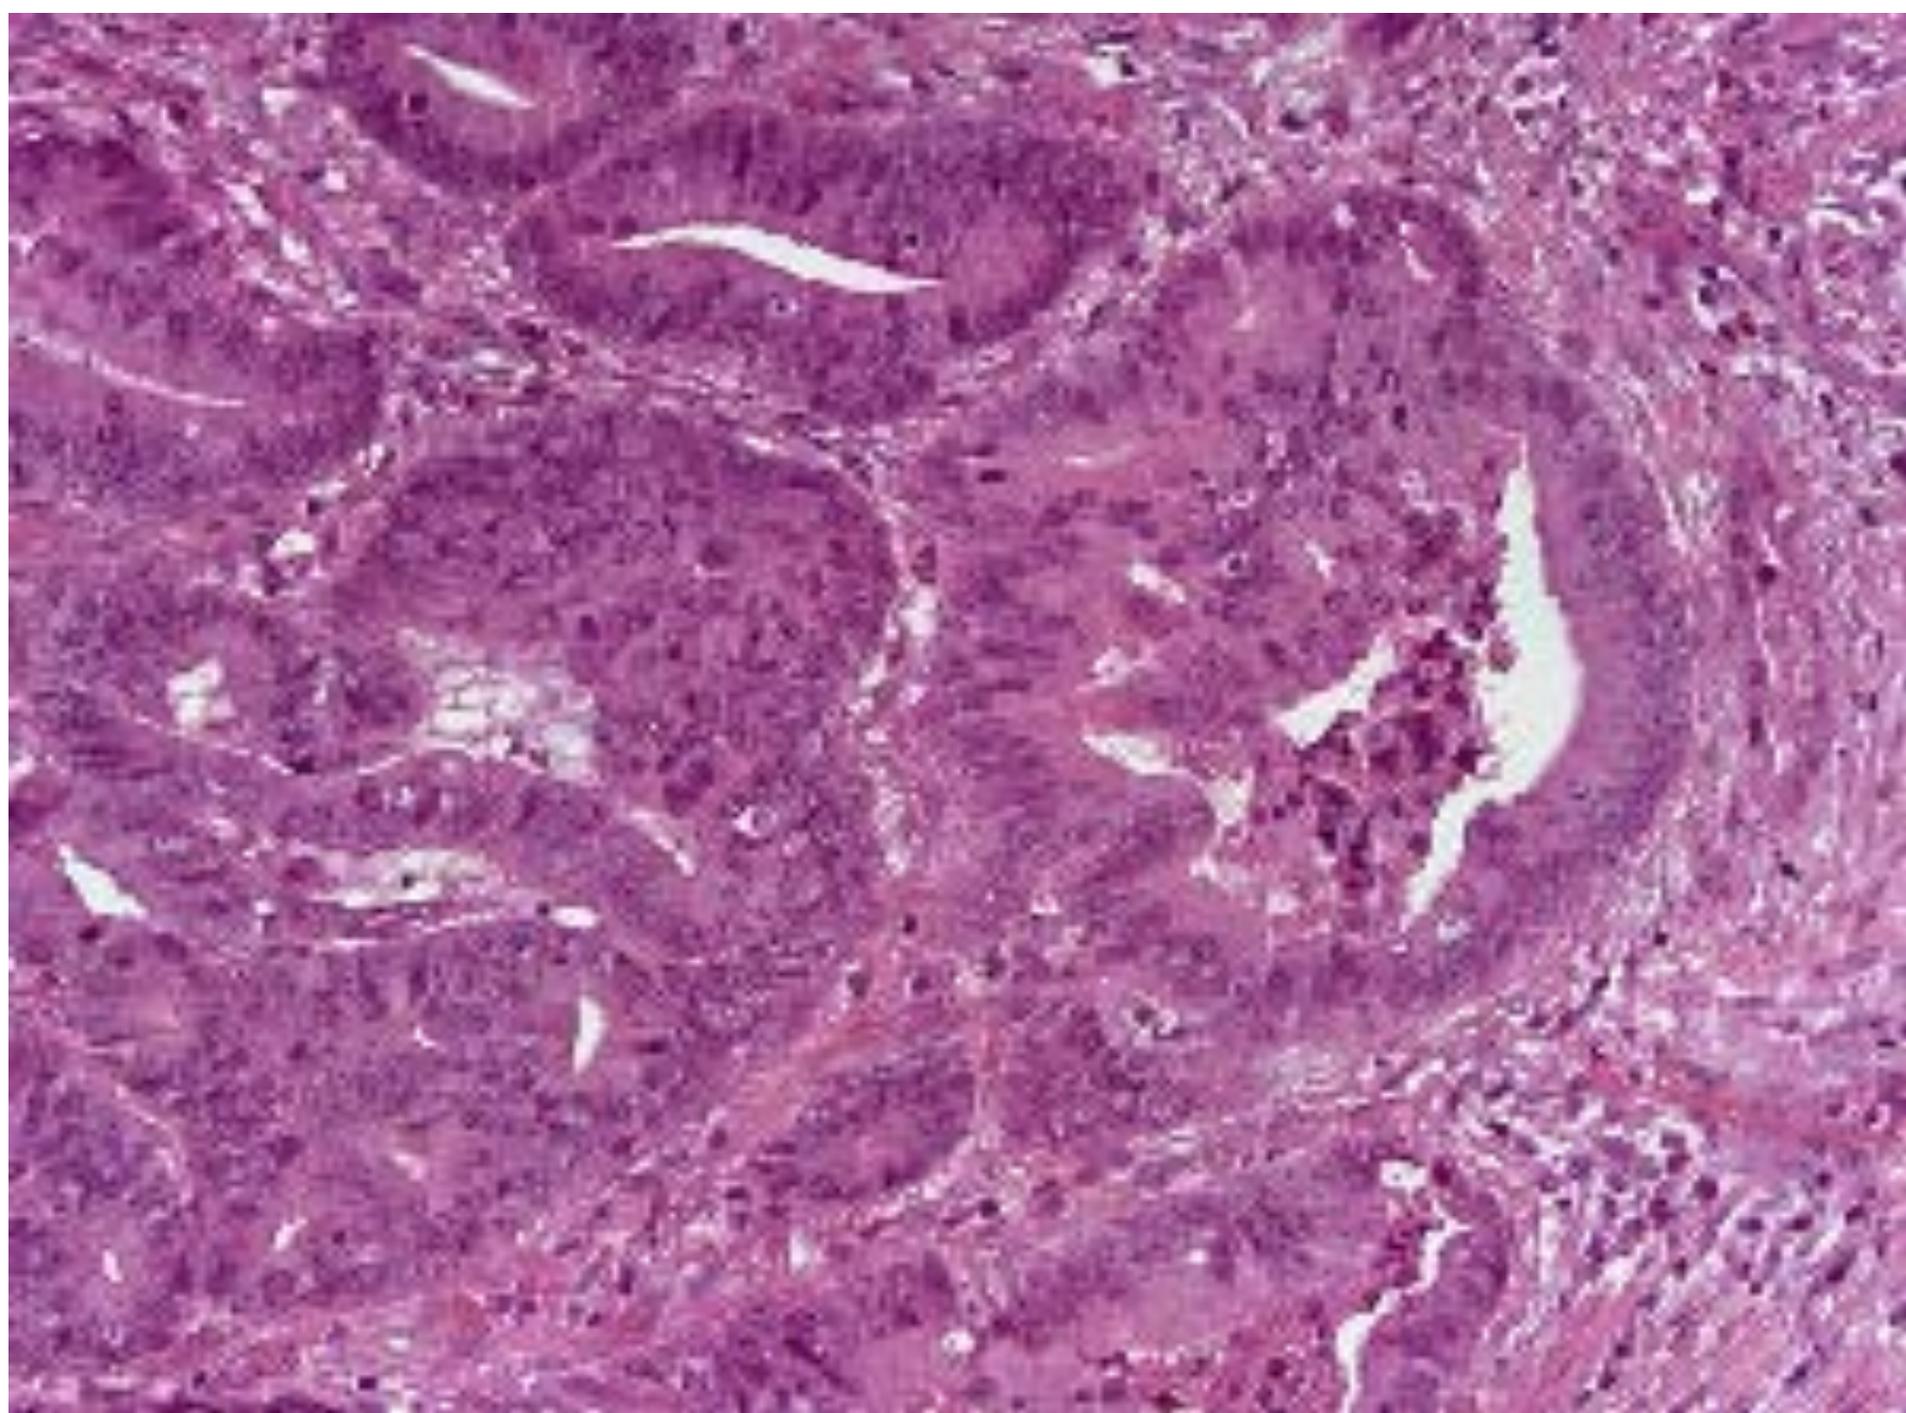

Clinicopathological characteristics

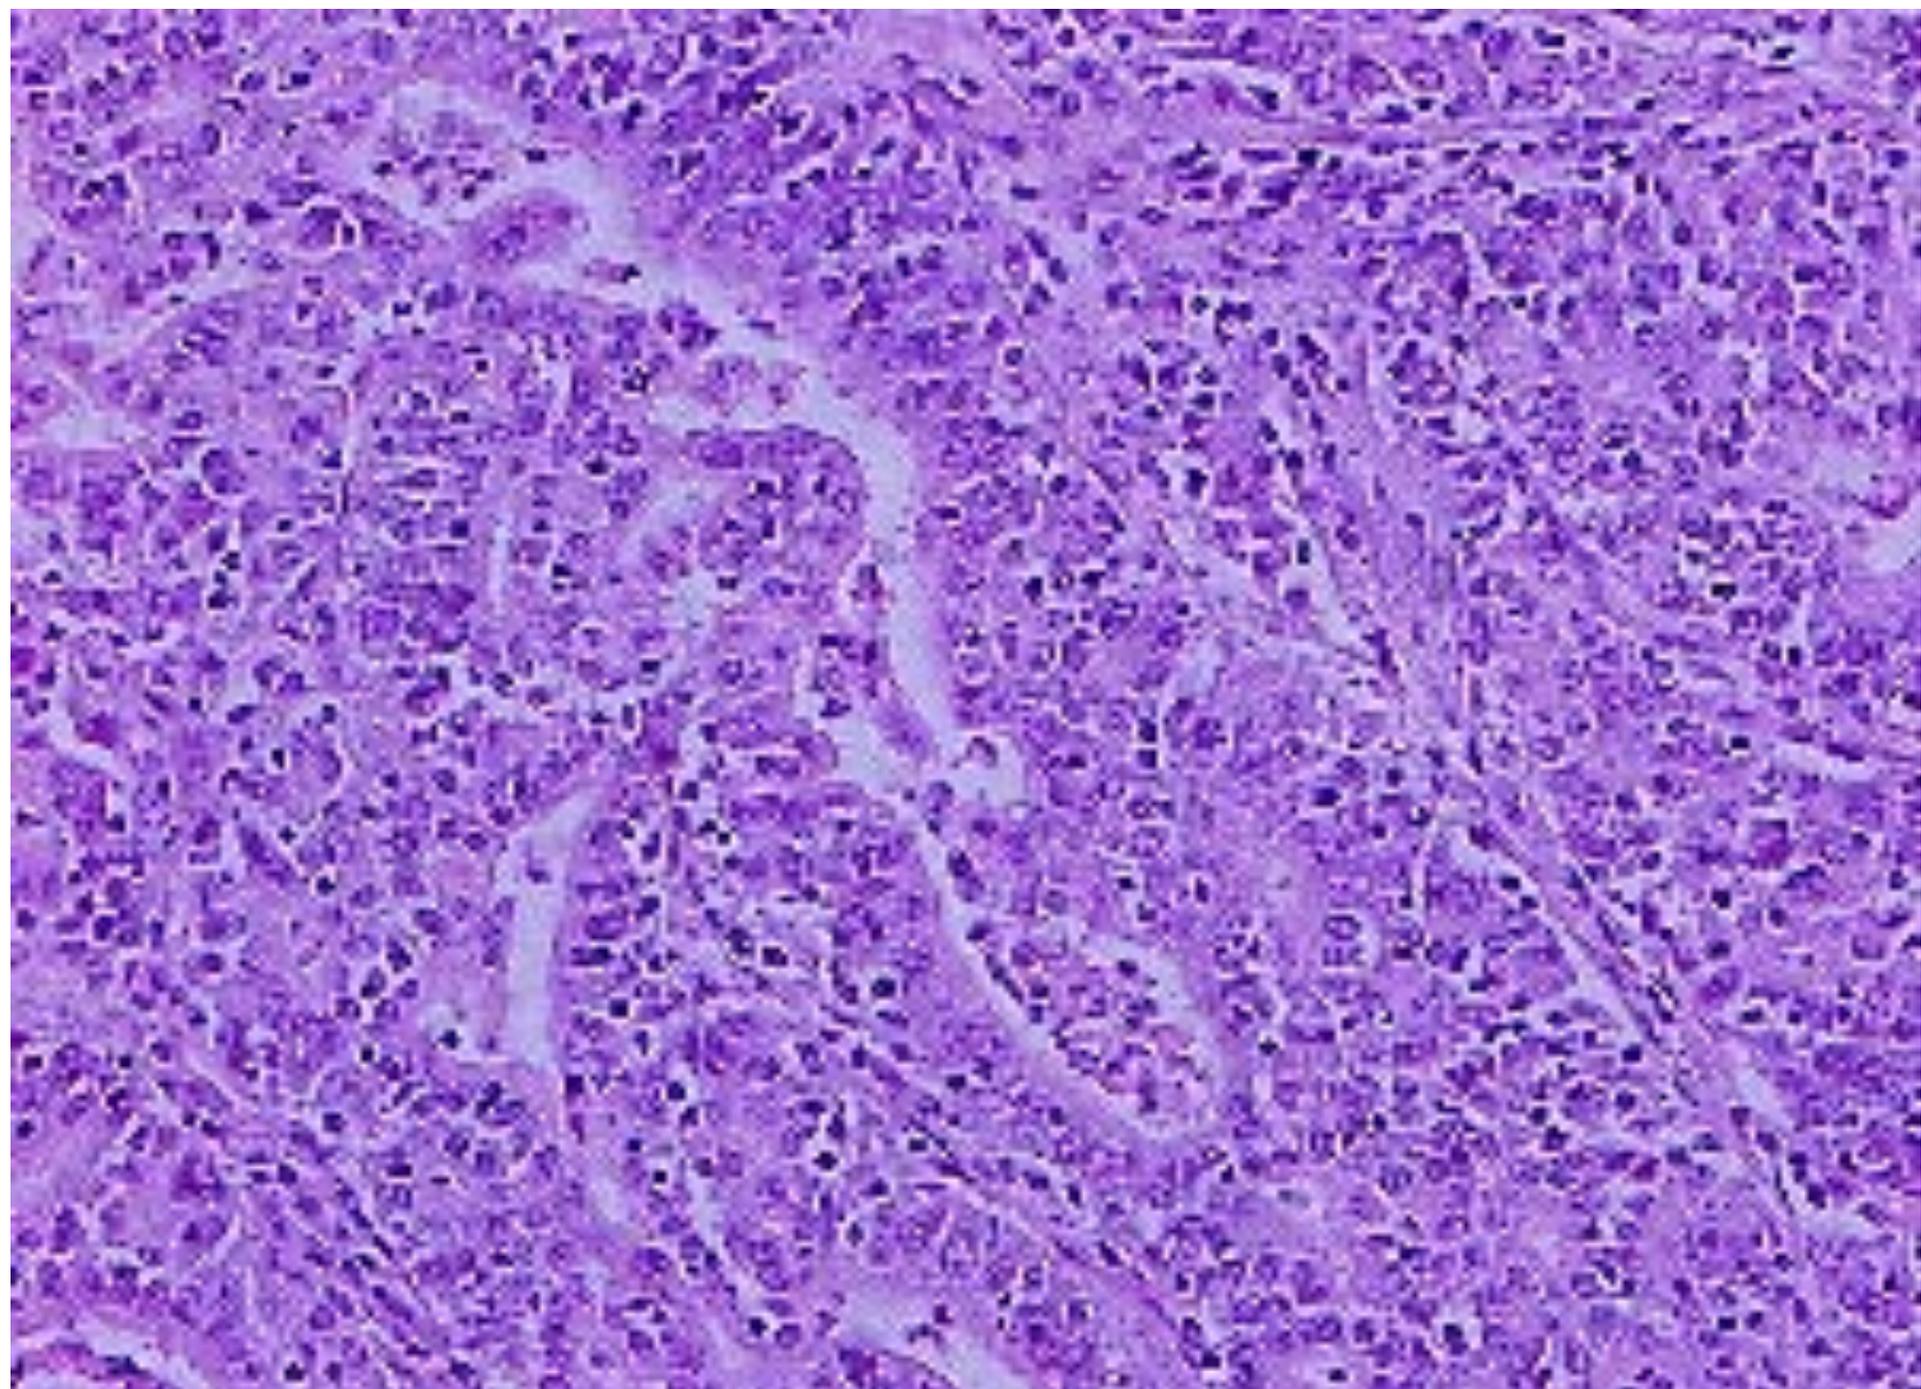

Patients with Lynch syndrome usually present with:

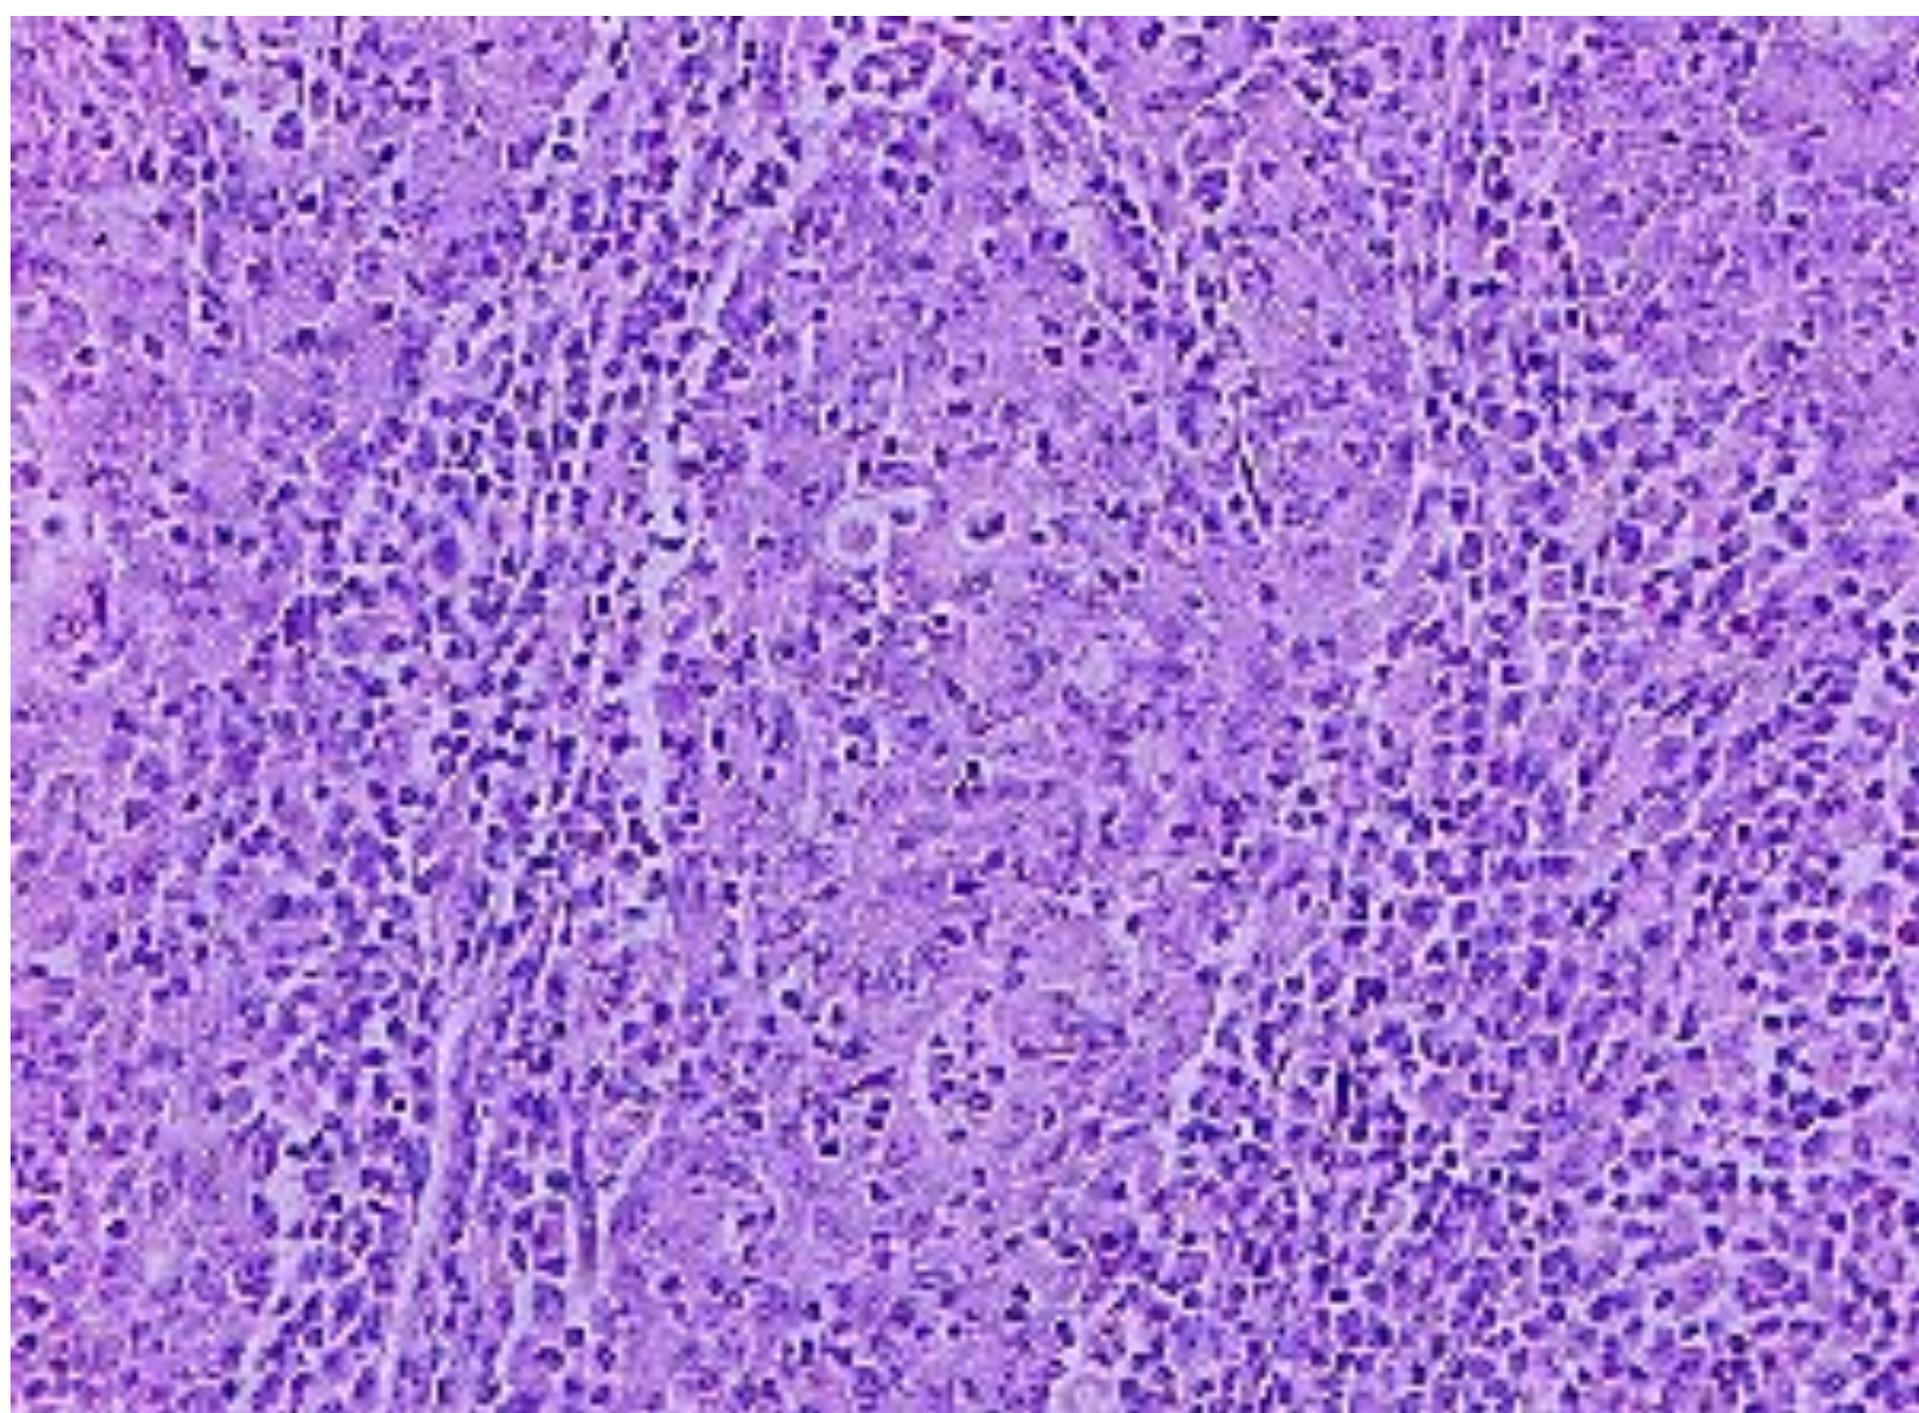

- adenocarcinoma of the proximal colon
- with or without synchronous or metachronous CRC or other malignancy typical of the syndrome (e.g. skin, stomach, urinary tract, biliary tree or brain and in women endometrial and ovarian carcinomas)

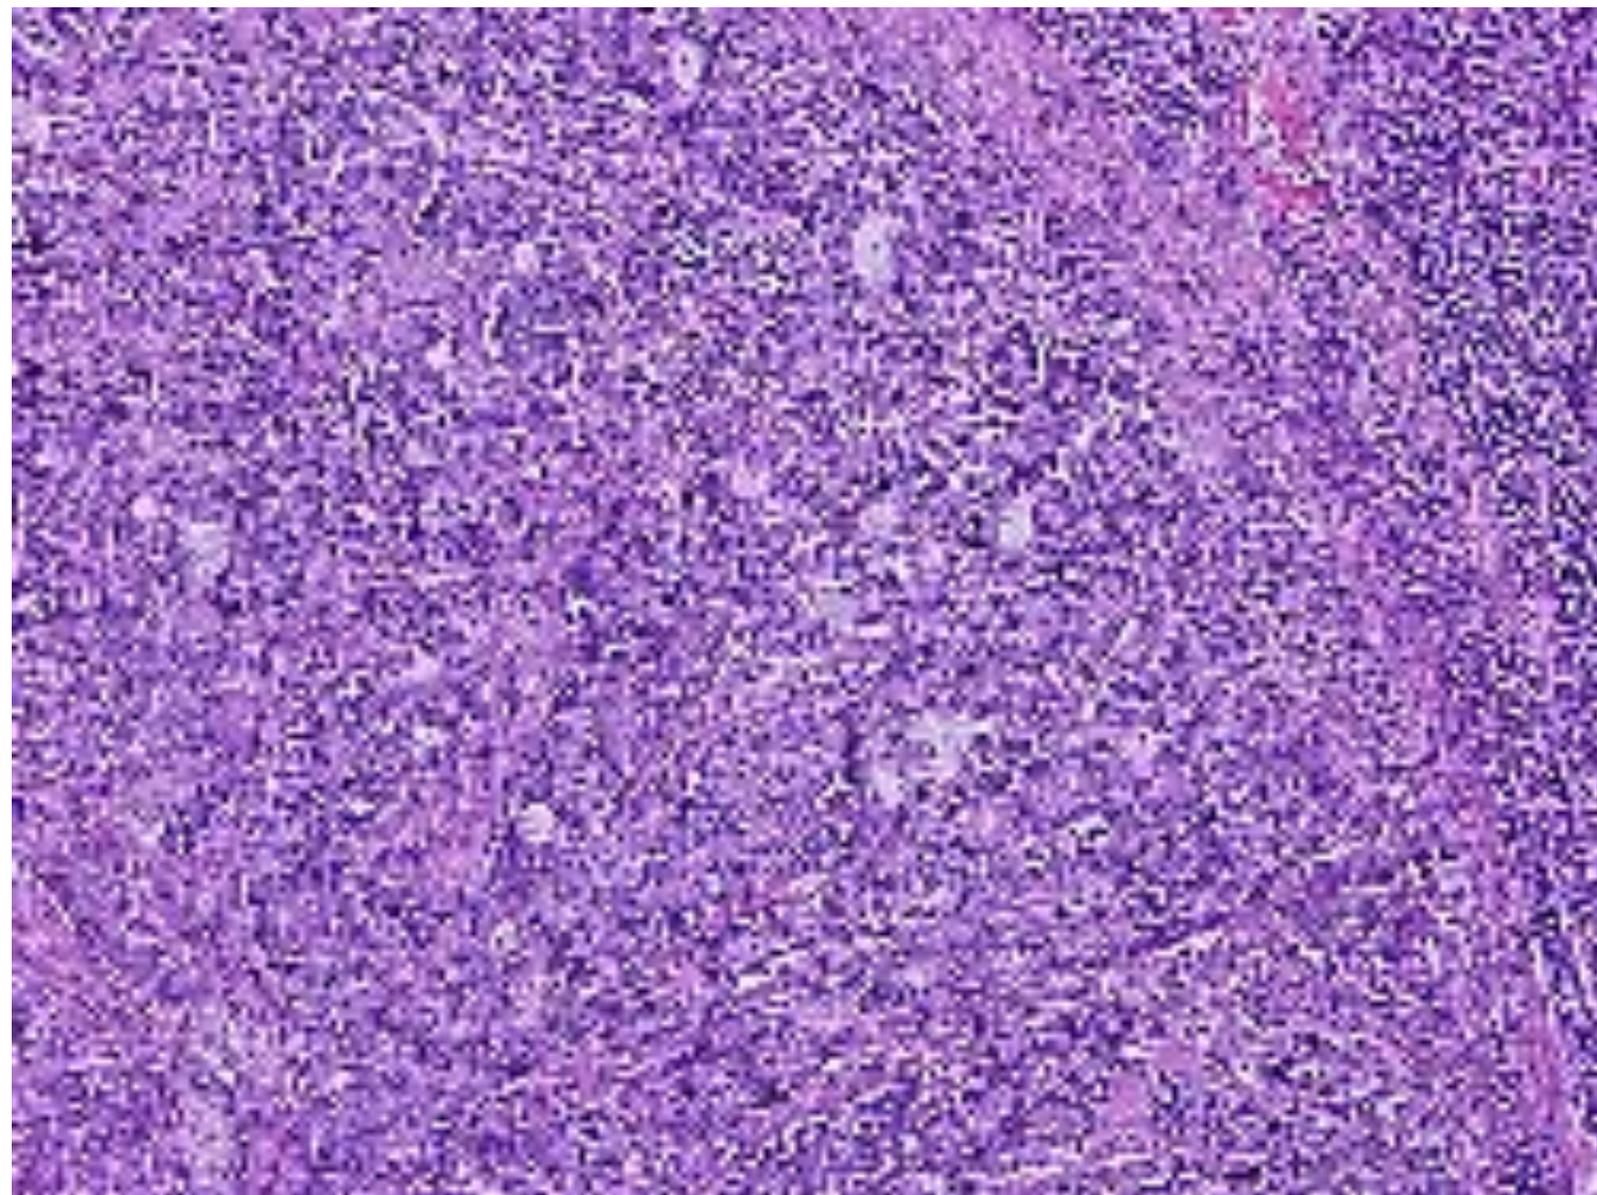

The set of clinical and pathologic criteria for identification of patients with high probability of Lynch syndrome constitutes the revised Bethesda guidelines

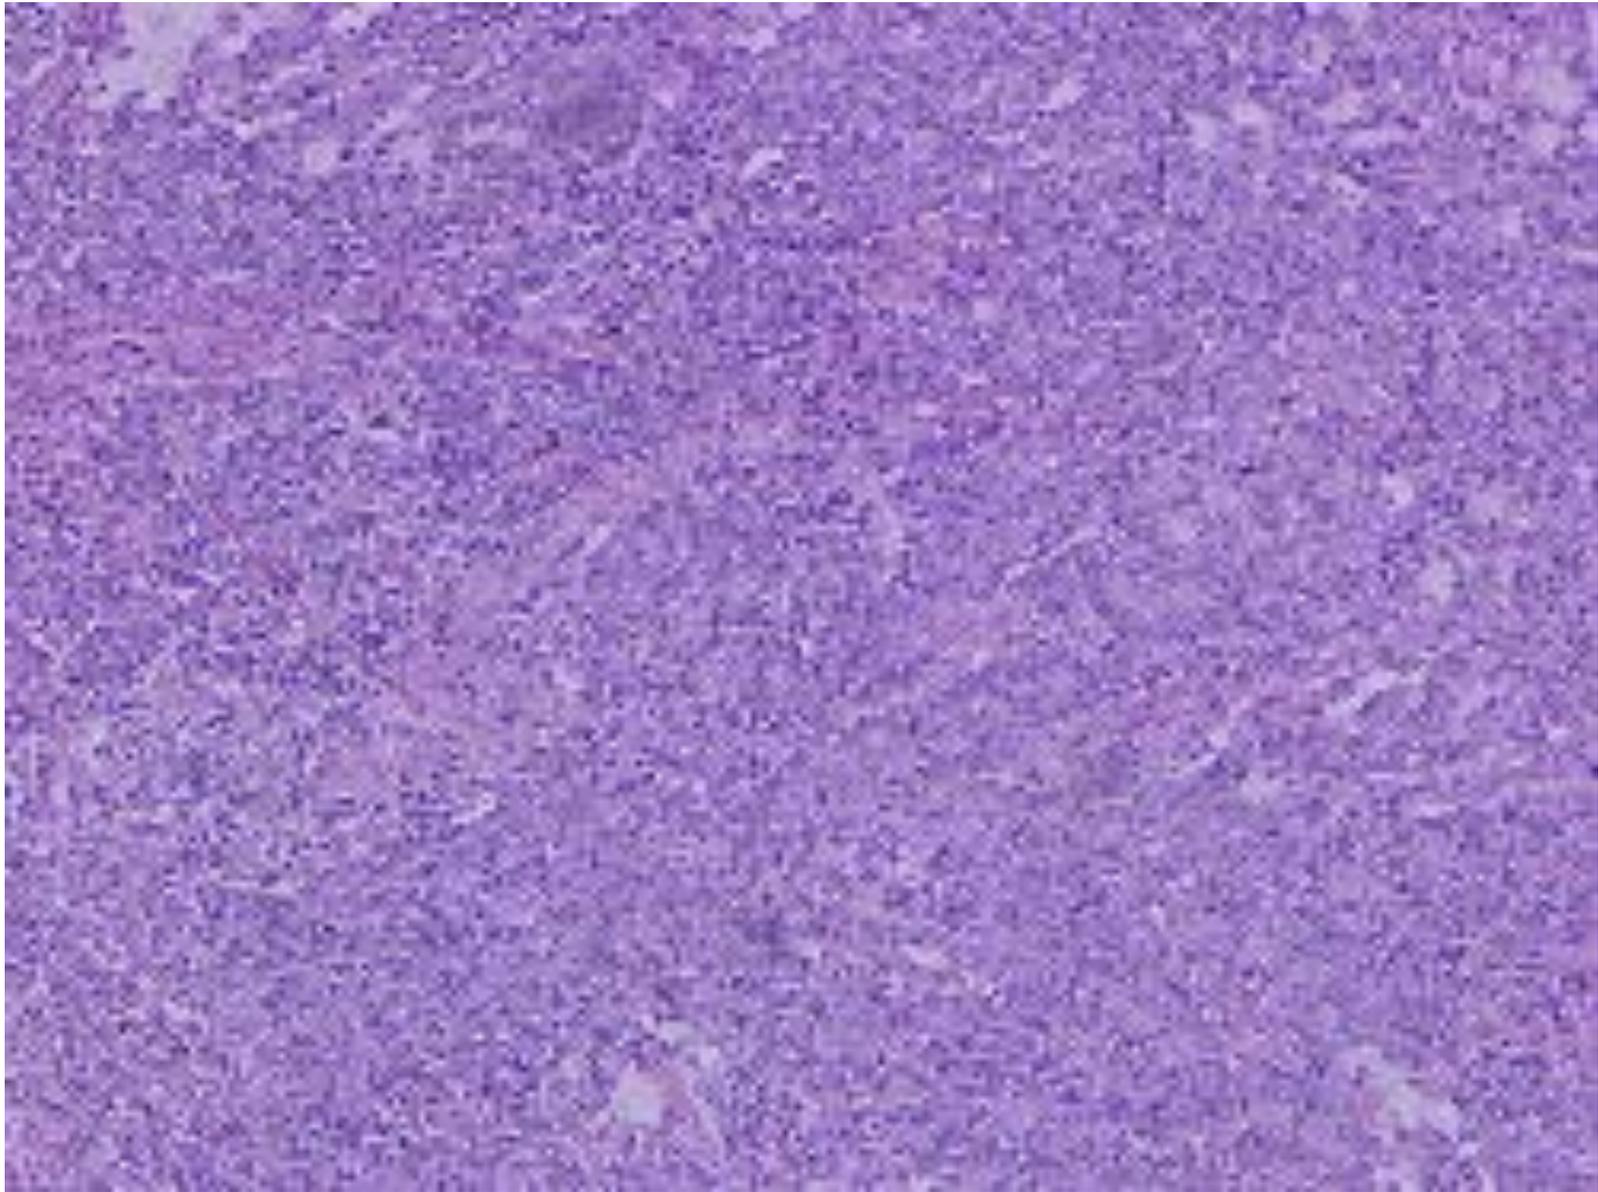

In applying these criteria, practicing pathologists need to recognize the occurrence of CRC in a patient with the history of other tumors characteristic of Lynch syndrome and to recognize characteristic morphology of MSI-H adenocarcinomas
