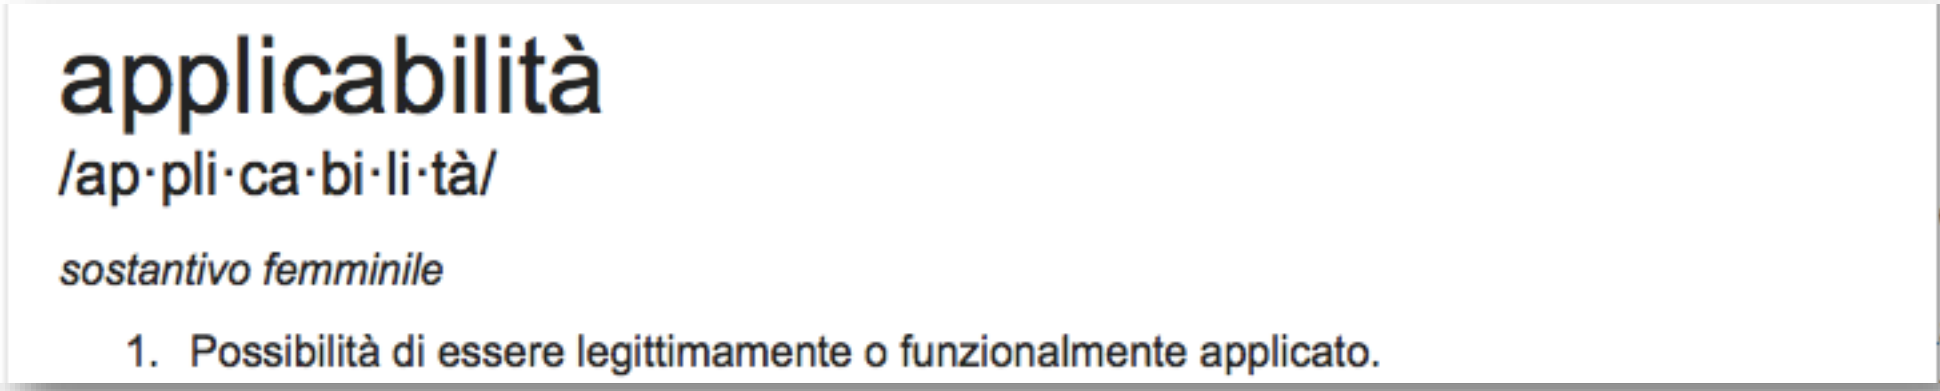
Applicability (or better applicabilità): what does it actually mean?

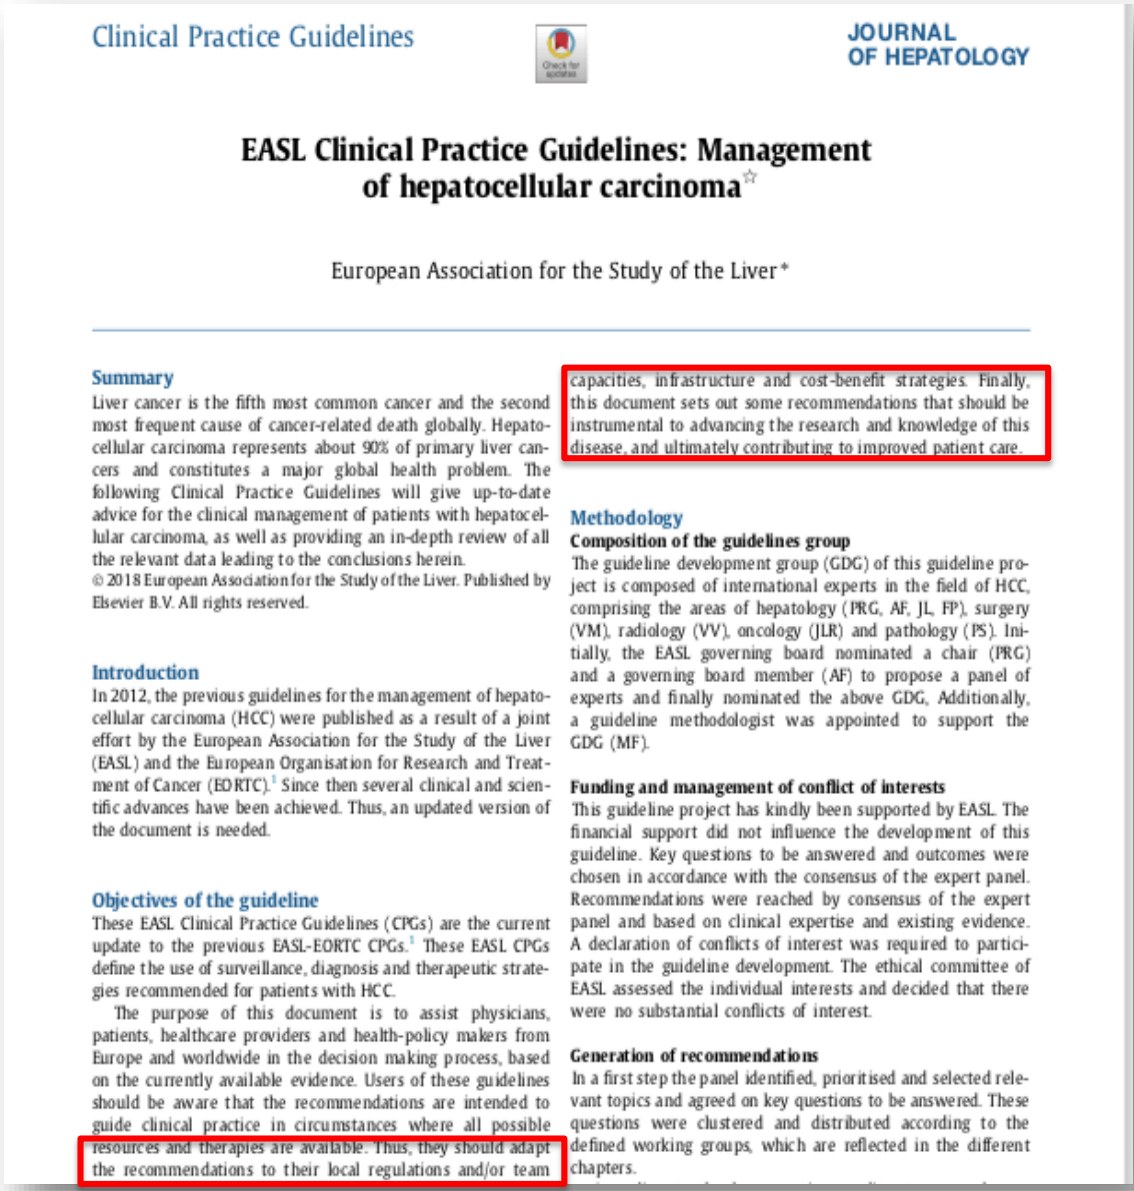


applicabilità

/ap·pli·ca·bi·li·tà/

sostantivo femminile

1. Possibilità di essere legittimamente o funzionalmente applicato.



Clinical Practice Guidelines

JOURNAL OF HEPATOLOGY

EASL Clinical Practice Guidelines: Management of hepatocellular carcinoma☆

European Association for the Study of the Liver*

Summary

Liver cancer is the fifth most common cancer and the second most frequent cause of cancer-related death globally. Hepatocellular carcinoma represents about 90% of primary liver cancers and constitutes a major global health problem. The following Clinical Practice Guidelines will give up-to-date advice for the clinical management of patients with hepatocellular carcinoma, as well as providing an in-depth review of all the relevant data leading to the conclusions herein.

Introduction

In 2012, the previous guidelines for the management of hepatocellular carcinoma (HCC) were published as a result of a joint effort by the European Association for the Study of the Liver (EASL) and the European Organisation for Research and Treatment of Cancer (EORTC).[1] Since then several clinical and scientific advances have been achieved. Thus, an updated version of the document is needed.

Objectives of the guideline

These EASL Clinical Practice Guidelines (CPGs) are the current update to the previous EASL-EORTC CPGs.[1] These EASL CPGs define the use of surveillance, diagnosis and therapeutic strategies recommended for patients with HCC.

The purpose of this document is to assist physicians, patients, healthcare providers and health-policy makers from Europe and worldwide in the decision making process, based on the currently available evidence. Users of these guidelines should be aware that the recommendations are intended to guide clinical practice in circumstances where all possible resources and therapies are available. Thus, they should adapt the recommendations to their local regulations and/or team capacities, infrastructure and cost-benefit strategies. Finally, this document sets out some recommendations that should be instrumental to advancing the research and knowledge of this disease, and ultimately contributing to improved patient care.

Methodology

Composition of the guidelines group

The guideline development group (GDG) of this guideline project is composed of international experts in the field of HCC, comprising the areas of hepatology (PRG, AF, JL, FP), surgery (VM), radiology (VV), oncology (JLR) and pathology (PS). Initially, the EASL governing board nominated a chair (PRG) and a governing board member (AF) to propose a panel of experts and finally nominated the above GDG. Additionally, a guideline methodologist was appointed to support the GDG (MF).

Funding and management of conflict of interests

This guideline project has kindly been supported by EASL. The financial support did not influence the development of this guideline. Key questions to be answered and outcomes were chosen in accordance with the consensus of the expert panel. Recommendations were reached by consensus of the expert panel and based on clinical expertise and existing evidence. A declaration of conflicts of interest was required to participate in the guideline development. The ethical committee of EASL assessed the individual interests and decided that there were no substantial conflicts of interest.

Generation of recommendations

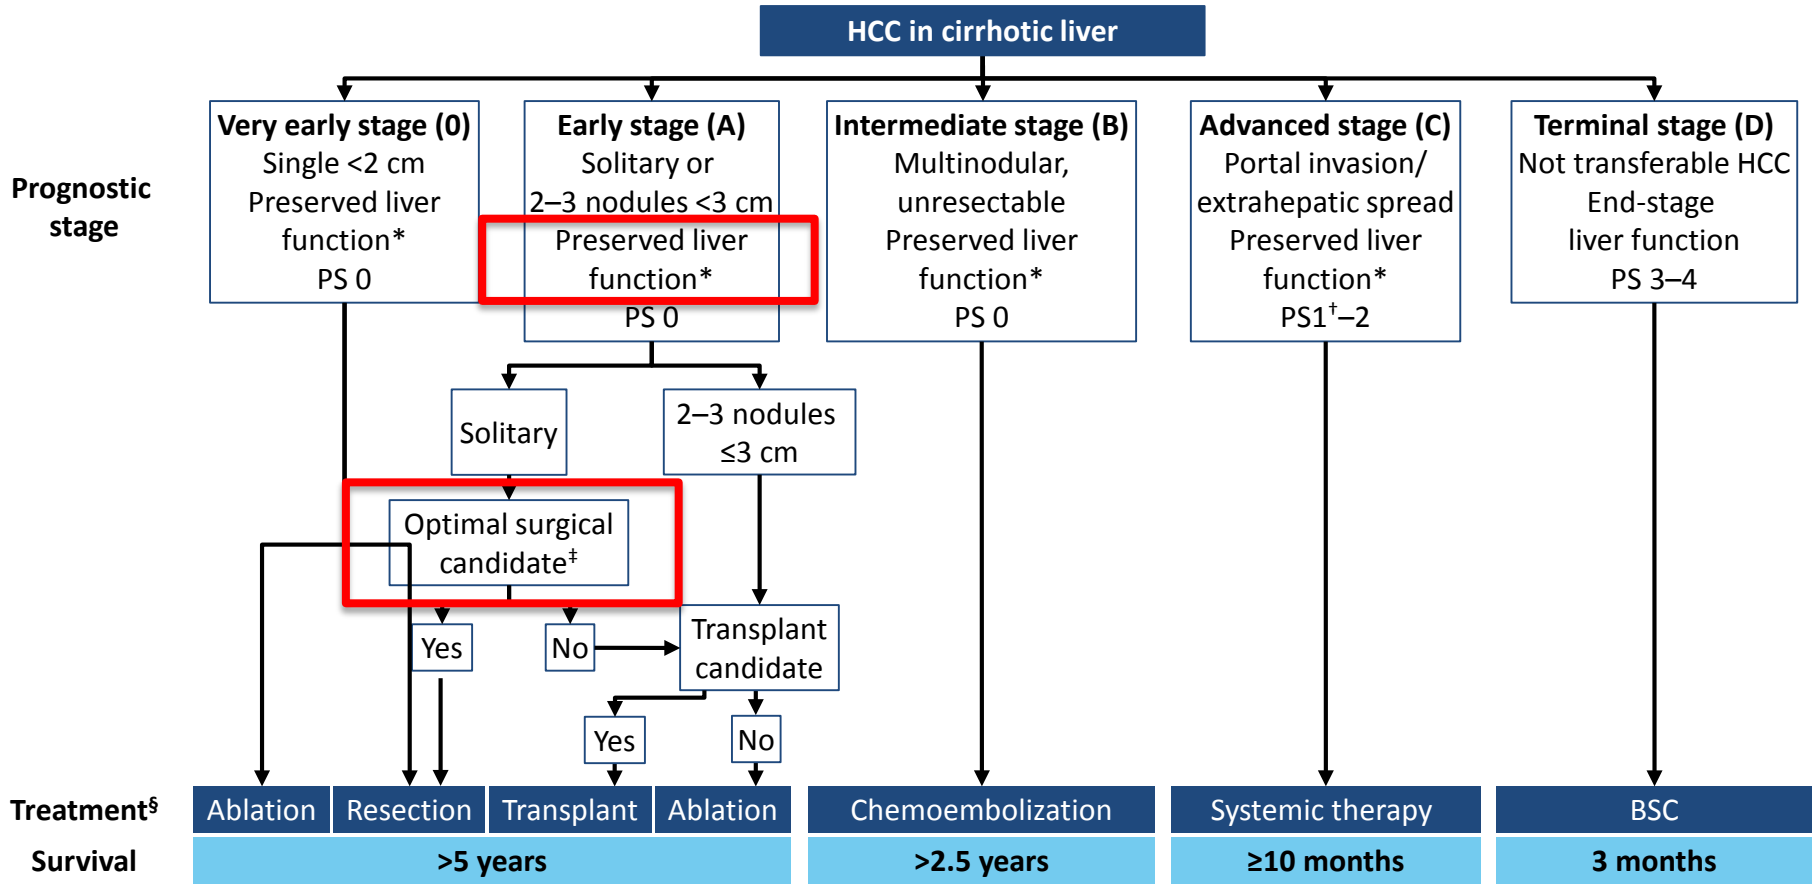
In a first step the panel identified, prioritised and selected relevant topics and agreed on key questions to be answered. These questions were clustered and distributed according to the defined working groups, which are reflected in the different chapters.

Physicians should adapt the recommendations to their local regulations and/or team capacities, infrastructure and cost-benefit strategies….

EASL HCC Committee, J Hepatology 2018

Applicability: surgery

Surgery in the early stage



EASL HCC Committee, J Hepatology 2018

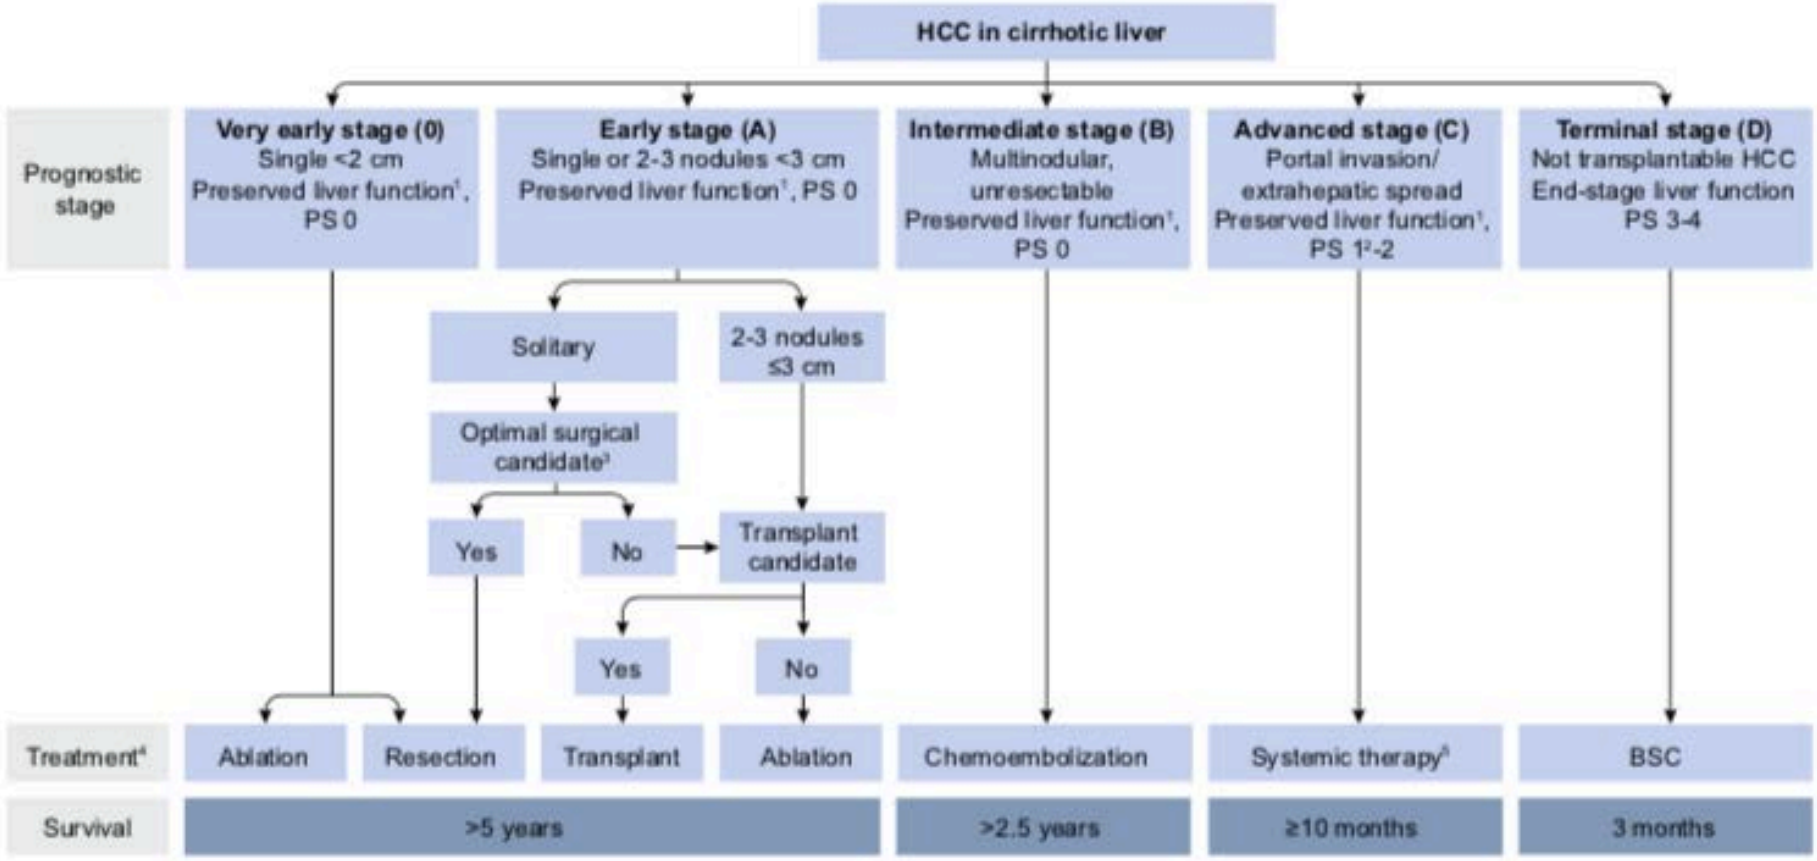


Fig. 3. Modified BCLC staging system and treatment strategy. [1]"**Preserved liver function**" refers to Child-Pugh A without any ascites, considered conditions to obtain optimal outcomes. This prerequisite applies to all treatment options apart from transplantation, that is instead addressed primarily to patients with decompensated or end-stage liver function. [2]**PS 1** refers to tumour induced (as per physician opinion) modification of performance capacity. [3]**Optimal surgical candidacy** is based on a multiparametric evaluation including compensated Child-Pugh class A liver function with MELD score <10, to be matched with grade of portal hypertension, acceptable amount of remaining parenchyma and possibility to adopt a laparoscopic/minimally invasive approach. The combination of the previous factors should lead to an expected perioperative mortality <3% and morbidity <20% including a postsurgical severe liver failure incidence <5%. [4]The **stage migration strategy** is a therapeutic choice by which a treatment theoretically recommended for a different stage is selected as best 1st line treatment option. Usually it is applied with a left to right direction in the scheme (*i.e.* offering the effective treatment option recommended for the subsequent more advanced tumour stage rather than that forecasted for that specific stage). This occurs when patients are not suitable for their first line therapy. However, in highly selected patients, with parameters close to the thresholds defining the previous stage, a right to left migration strategy (*i.e.* a therapy recommended for earlier stages) could be anyhow the best opportunity, pending multidisciplinary decision. [5]As of 2017 sorafenib has been shown to be effective in first line, while regorafenib is effective in second line in case of radiological progression under sorafenib. Lenvatinib has been shown to be non-inferior to sorafenib in first line, but no effective second line option after lenvatinib has been explored. Cabozantinib has been demonstrated to be superior to placebo in 2nd or 3rd line with an improvement of OS from eight months (placebo) to 10.2 months (ASCO GI 2018). Nivolumab has been approved in second line by FDA but not EMA based on uncontrolled phase II data. ASCO, American Society of Clinical Oncology; BCLC, Barcelona Clinic Liver Cancer; EMA, European Medicines Agency; FDA, Food and Drug Administration; MELD, model for end-stage liver disease; PS, performace status; OS, overall survival. Modified with permission from[87].

Preserved liver function

refers to Child-Pugh A without any ascites

Optimal surgical candidate

Optimal surgical candidacy is based on a multiparametric evaluation including:

- compensated Child-Pugh class A liver function with MELD score <10

To be matched with:

- grade of portal hypertension
- acceptable amount of remaining parenchyma
- possibility to adopt a laparoscopic/minimally invasive approach

Liver resection in cirrhotic liver

Several refinements in techniques, perioperative management and case selection have improved surgical interventions for liver cancer in patients with chronic liver disease and cirrhosis. Since no single surgical modality fits all HCC presentations, a multidisciplinary approach to surgical intervention is mandatory. This should be focussed on the key conditions affecting decision making in the area of surgical HCC, resulting in a multi-parametric approach to cancer and non-cancer components in the single patient. Criteria presented in the previous European Association for the Study of the Liver (EASL)/European Organisation for Research and Treatment of Cancer (EORTC) Clinical Practice Guidelines in 2012[1] (*i.e.* solitary tumours and very well-preserved liver function, hepatic vein to portal system gradient ≤10 mmHg or platelet count ≥100,000/ml) describe the "ideal" candidates for LR in cirrhosis. Such prescription remains confirmed, especially in a non-experienced context.

However, in the last few years patients exceeding one or more of the described criteria have been approached with LR in experienced centres, providing accurate balance of the relative weight of each determinant of prognosis. This has been enabled by general optimisation of surgical technique, pre-resection imaging planning, ultrasonic and bipolar dissector devices, intermittent hilar clamping (Pringle manoeuvre), low central venous pressure maintenance, mini-invasive approaches and intensive post-operative management. Indirect confirmation of improved perioperative management of the surgical patient emerges from the reported decrease in blood transfusion during LR in cirrhosis, from 80% to 90% to less than 10% in two decades.[332] Overall, outcome results achieved in patients undergoing LR in experienced centres (*i.e.* post-operative mortality and severe post-surgical morbidity of <3% and <30%, respectively) seem to favour the use of extended criteria for LR, namely of HCCs in which one or more conventional selection criteria for LR summarised in the 2012 EASL/EORTC Guidelines are not satisfied.

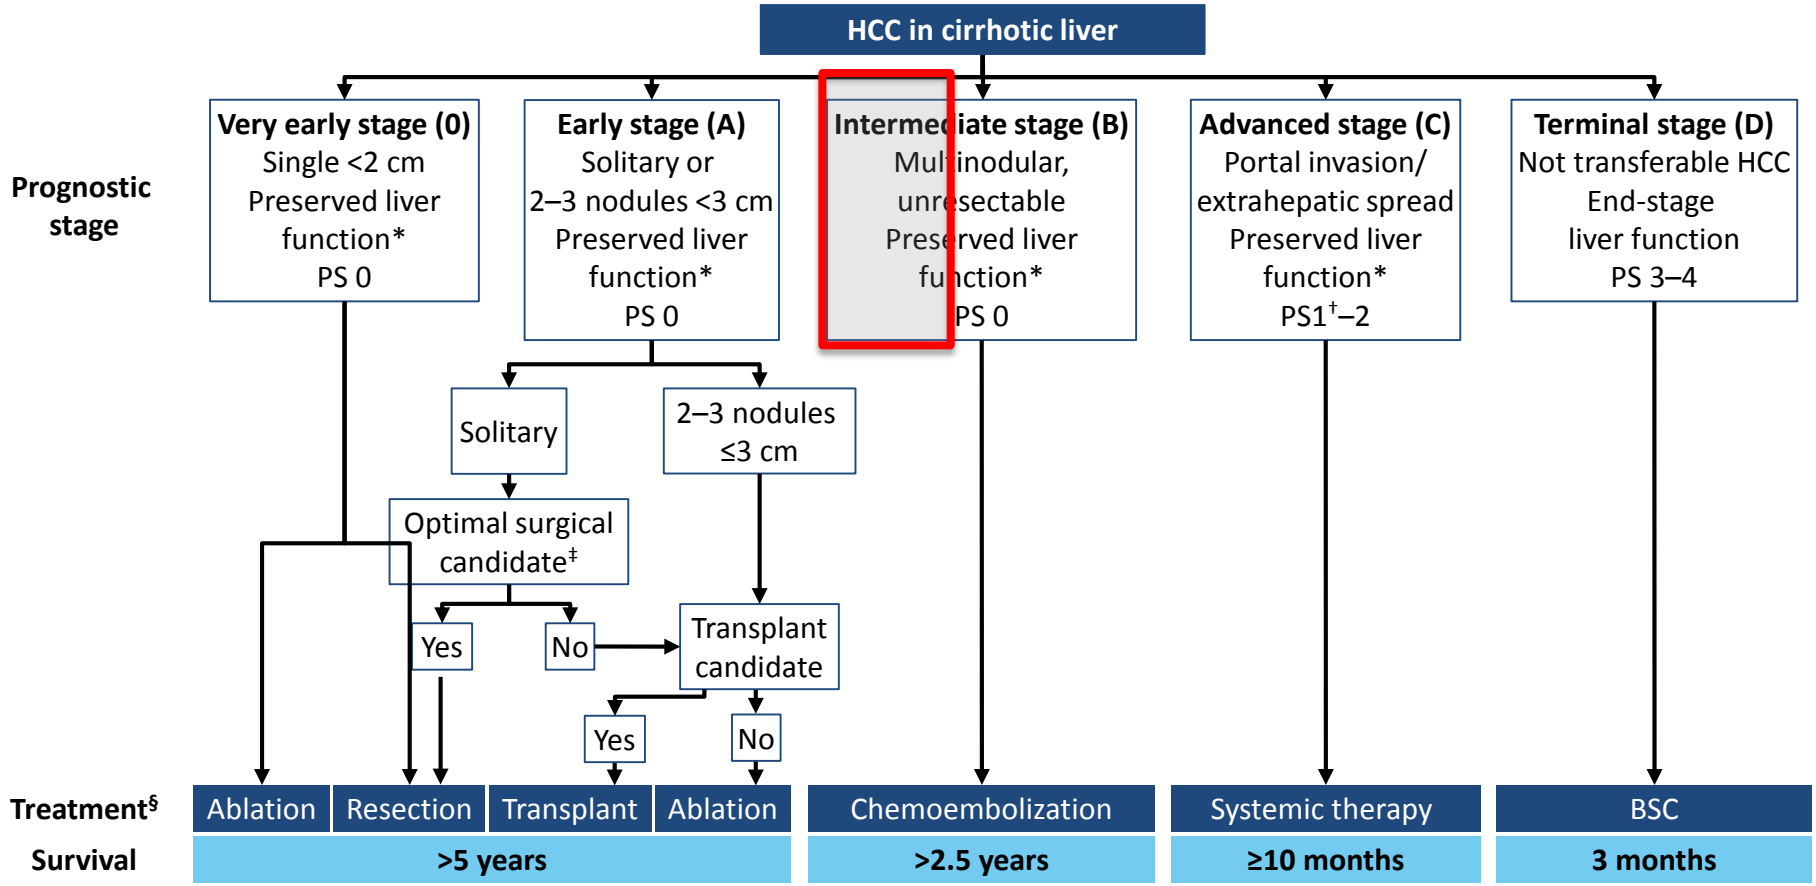
Surgery in the extended criteria = intermediate



EASL HCC Committee, J Hepatology 2018

post-operative liver decompensation.[298,355,356] That widens the curative perspective offered by modern LR approaches, particularly in hepatitis C virus (HCV)-related cirrhotic patients in which pre/post-resection treatment with direct-acting antivirals (DAAs) may optimise liver function control.

On top of the previous considerations, LR for HCC – as with any surgical procedure –patients' general condition, performance status and co-morbidities must be considered ahead of any intervention. Age should not be a contraindication *per se*, if adequate performance status and no major co-morbidities are confirmed in patients undergoing LR for HCC. In particular, post-surgical survivals compared to age-sex-matched reference populations suggest that LR can be offered in patients >70 years old, who are in fact exposed to a smaller loss of their individual lifespan in comparison with their younger counterparts.[357]

When liver-preservation principles are met, and patient's general conditions have been scrutinised as permissive for surgical intervention, LR should be tailored on HCC characteristics and presentation. In this respect, at least four major considerations should contribute to decide the best approach to LR in case of single HCC in cirrhosis:

a. Tumour size and intrahepatic tumour location influence decision on surgical approach. For single HCCs ≤2 cm deeply/centrally located, radiofrequency ablation (RFA) offers competitive results with respect to LR (see paragraph on local ablation). Conversely, laparoscopic-robotic LR for HCC located in superficial-peripheral positions of the liver provides optimal survival outcomes while minimising complications and hospital stay (Fig. 6);

Clinical Practice Guidelines

On top of the previous considerations, LR for HCC must be considered ahead of any intervention…

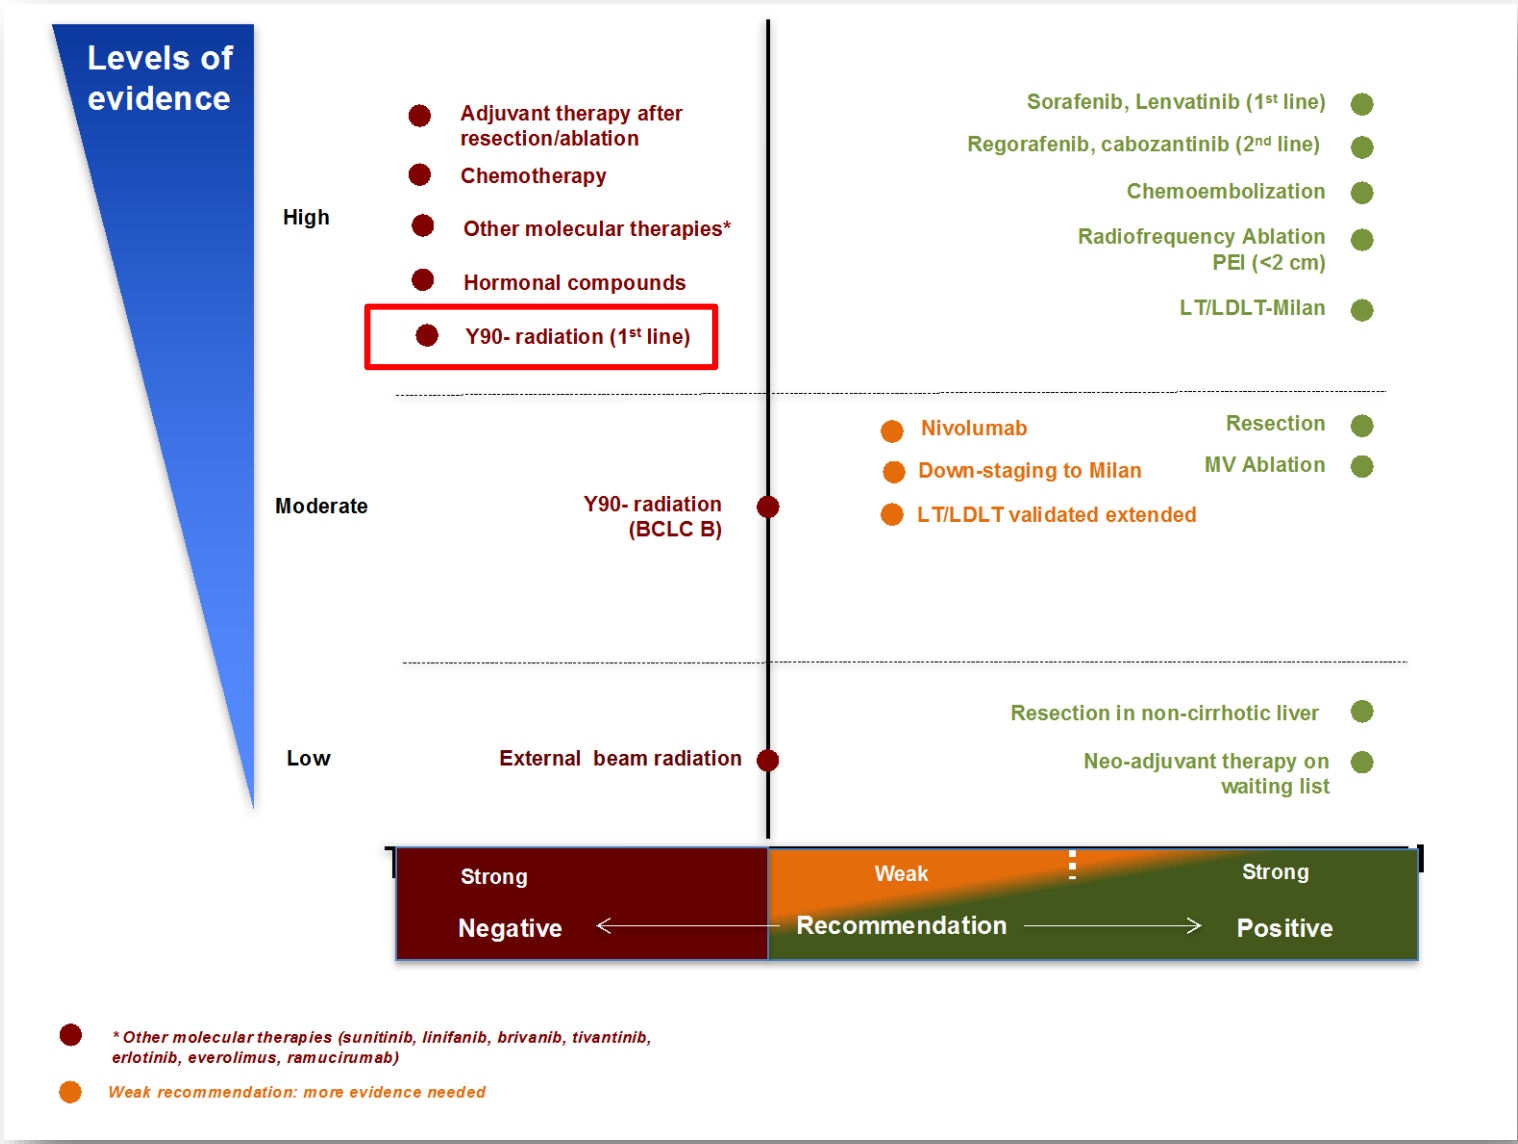
EASL HCC GUIDELINES 2018: the place for TARE



EASL HCC Committee, J Hepatology 2018

TARE in the clinical practical guidelines

SIRT vs. sorafenib

One of the most common indications of SIRT is treatment of patients with locally advanced HCC. Two RCTs comparing efficacy and safety in patients treated with SIRT *vs.* sorafenib have completed patient enrolment and have been presented.[556,557] In both studies, designed for superiority of SIRT, the primary endpoint was not reached as no statistically significant differences in OS were observed in intention-to-treat or per-protocol populations. In both studies, tumour response rate was significantly higher with SIRT, although this finding did not translate into longer survival. In both trials, the applicability of Y-90 was limited to 72–77% of patients because of treatment contraindications. In the SIRveNIB trial,[557] progression-free survival and time to progression were significantly higher in the SIRT group than in the sorafenib group in the treated population. In the SARAH trial,[556] the total and median number of treatment-related adverse events per patient were twice as frequent with sorafenib *vs.* SIRT including Grade ≥3 treatment-related adverse events. However, the course of the adverse event (rate of remission in the two arms) was not reported. A head-to-head RCT of SIRT *vs.* sorafenib is ongoing, and the added value of sorafenib in patients treated with SIRT is being evaluated in another RCT (SORAMIC trial). Another phase III clinical trial (STOP-HCC) evaluating yttrium-90 trans-arterial radioembolization (TheraSphere®) prior to sorafenib *vs.* Sorafenib alone in the treatment of patients with unresectable HCC is ongoing. At present, the survival benefit of SIRT compared to sorafenib in advanced HCC is still not proven, and its use either alone or in combination with systemic therapy should only be adopted after multidisciplinary board discussion.

Clinical Practice Guidelines

At present, the survival benefit of SIRT compared to sorafenib in advanced HCC is still not proven, and its use either alone or in combination with systemic therapy should only be adopted after multidisciplinary board discussion

STUDY CONCEPT

	SARAH	SIRVENIB

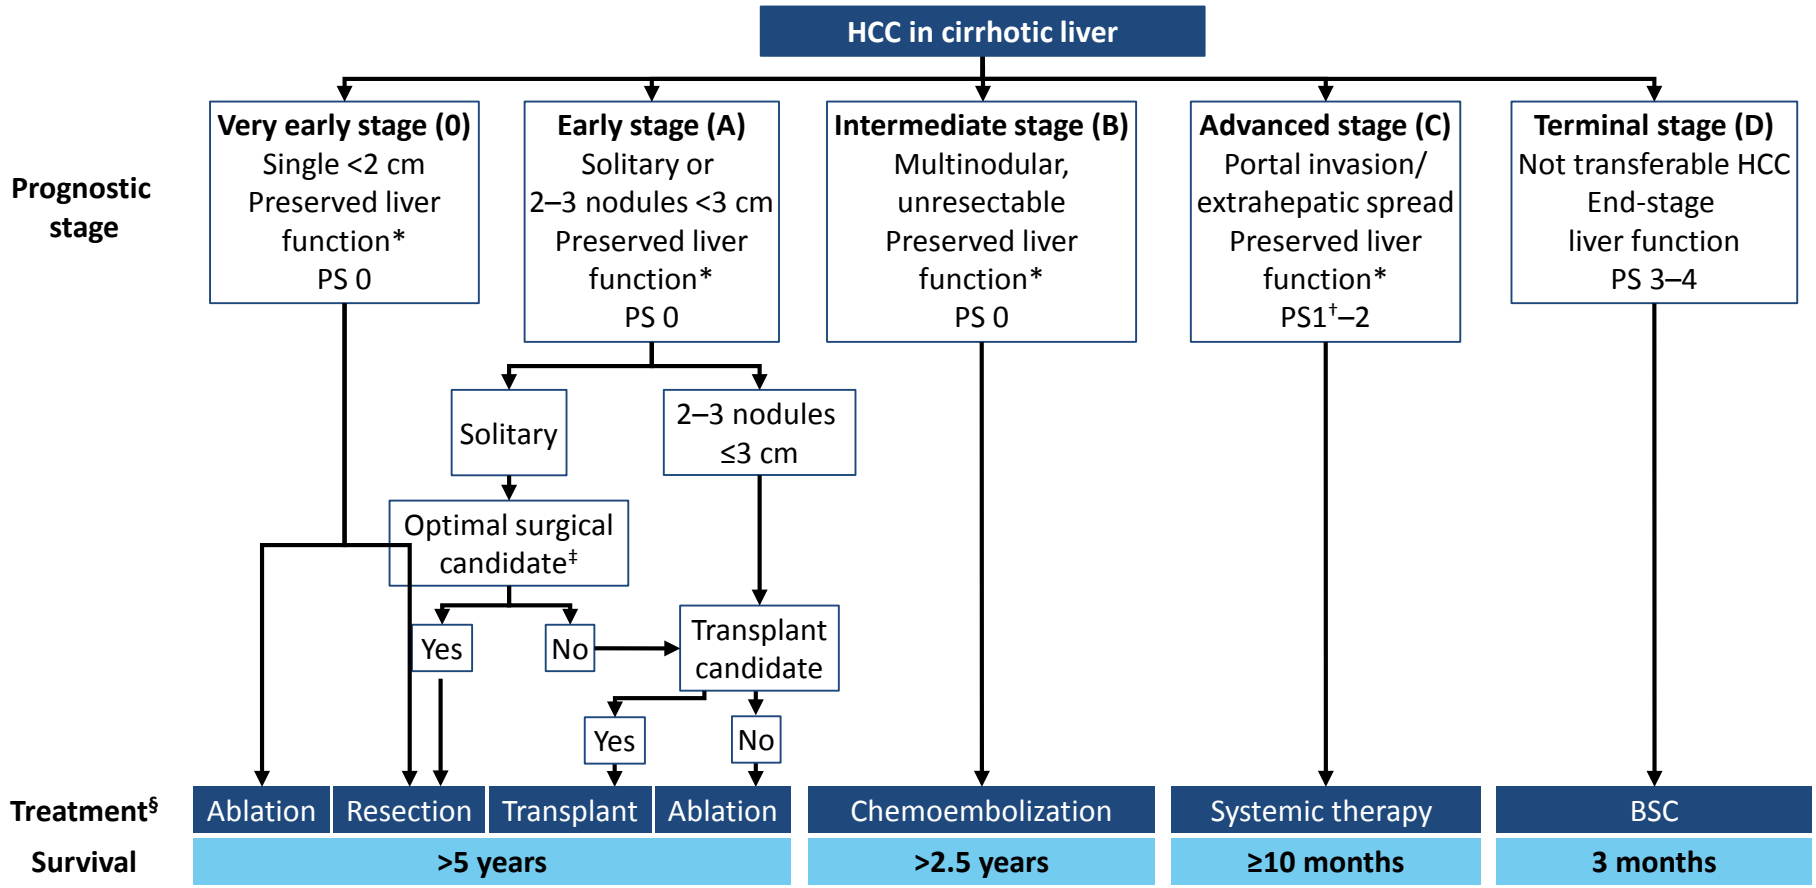
Applicability of systemic treatments



EASL HCC Committee, J Hepatology 2018

Clinical Practice Guidelines

Systemic therapies

Recommendations

- Sorafenib is the standard first-line systemic therapy for HCC. It is indicated for patients with well-preserved liver function (Child-Pugh A) and with advanced tumours (BCLC–C) or earlier stage tumours progressing upon or unsuitable for loco-regional therapies (**evidence high; recommendation strong**).
- Lenvatinib has been shown to be non-inferior to sorafenib and is also recommended in first-line therapy for HCC given its approval. It is indicated for patients with well-preserved liver function (Child-Pugh A class), good performance status and with advanced tumours – BCLC-C without main portal vein invasion – or those tumours progressing upon or unsuitable for loco-regional therapies (**evidence high; recommendation strong**).
- There are no clinical or molecular biomarkers established to predict response to first or second-line systemic treatments (**evidence moderate**).
- Regorafenib is recommended as second-line treatment for patients tolerating and progressing on sorafenib and with well-preserved liver function (Child-Pugh A class) and good performance status (**evidence high; recommendation strong**). Recently, Cabozantinib has

Sorafenib
safe applicability in selected Child Pugh B

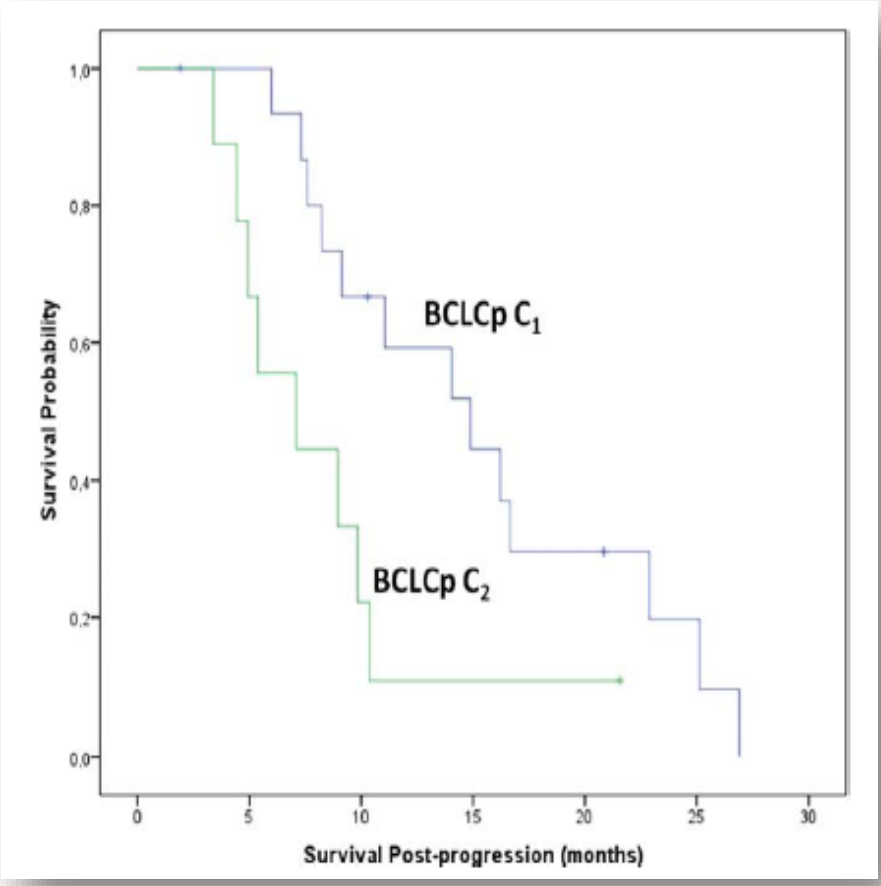
Lenvatinib
difficult applicability of a drug with advanced criteria exclusion, no second line treatment and higher reported serious AE

Regorafenib
recommended at whatever progression?
Clinical judgment of tumor progression based on availabilty of second line

EASL HCC Committee, J Hepatology 2018

mRECIST (radiological progression) or pattern of progression

BCLCp classification



Patients who progress to or within a C stage:

- BCLCp-C_1: with progression due to growth of existing nodules or new intrahepatic sites (14.9 months)
- BCLCp-C_2: with progression due to new extrahepatic lesion and/or vascular invasion (7.1 months)

BCLC, Barcelona Clinic Liver Cancer; BCLCp, BCLC upon progression.

Reig M et al. Hepatology 2013;58:2023–31.

mRECIST as they were intended to be

RECIST — learning from the past to build the future

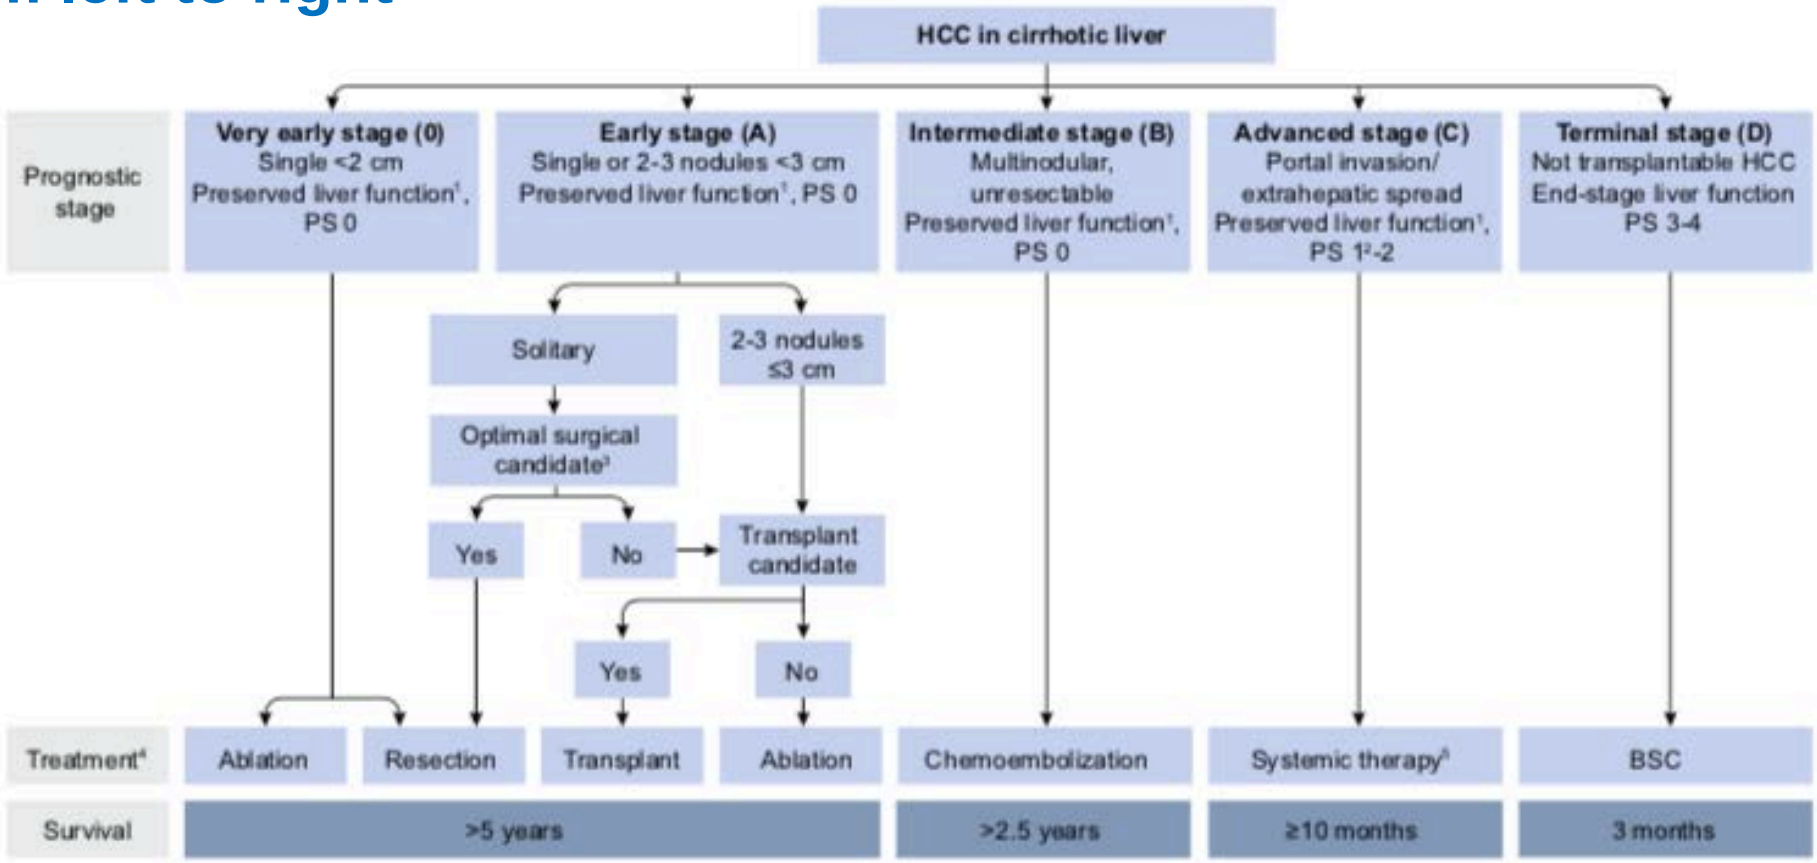
Saskia Litière, Sandra Collette, Elisabeth G. E. de Vries, Lesley Seymour and Jan Bogaerts

Indeed, RECIST was meant as a tool for clinical trials, not to replace common-sense clinical decision-making. Both in clinical trials and in clinical practice, treatment protocols can consider treatment beyond (RECIST) progression, if it provides clinical benefit to a particular patient.

Litière et al. Nat Rev Clin Oncol 2017;14:187-192

Applicability: stage migration

from left to right



The **stage migration strategy** is a therapeutic choice by which a treatment theoretically recommended for a particular stage is selected as best 1st line treatment option for an earlier stage

from right to left

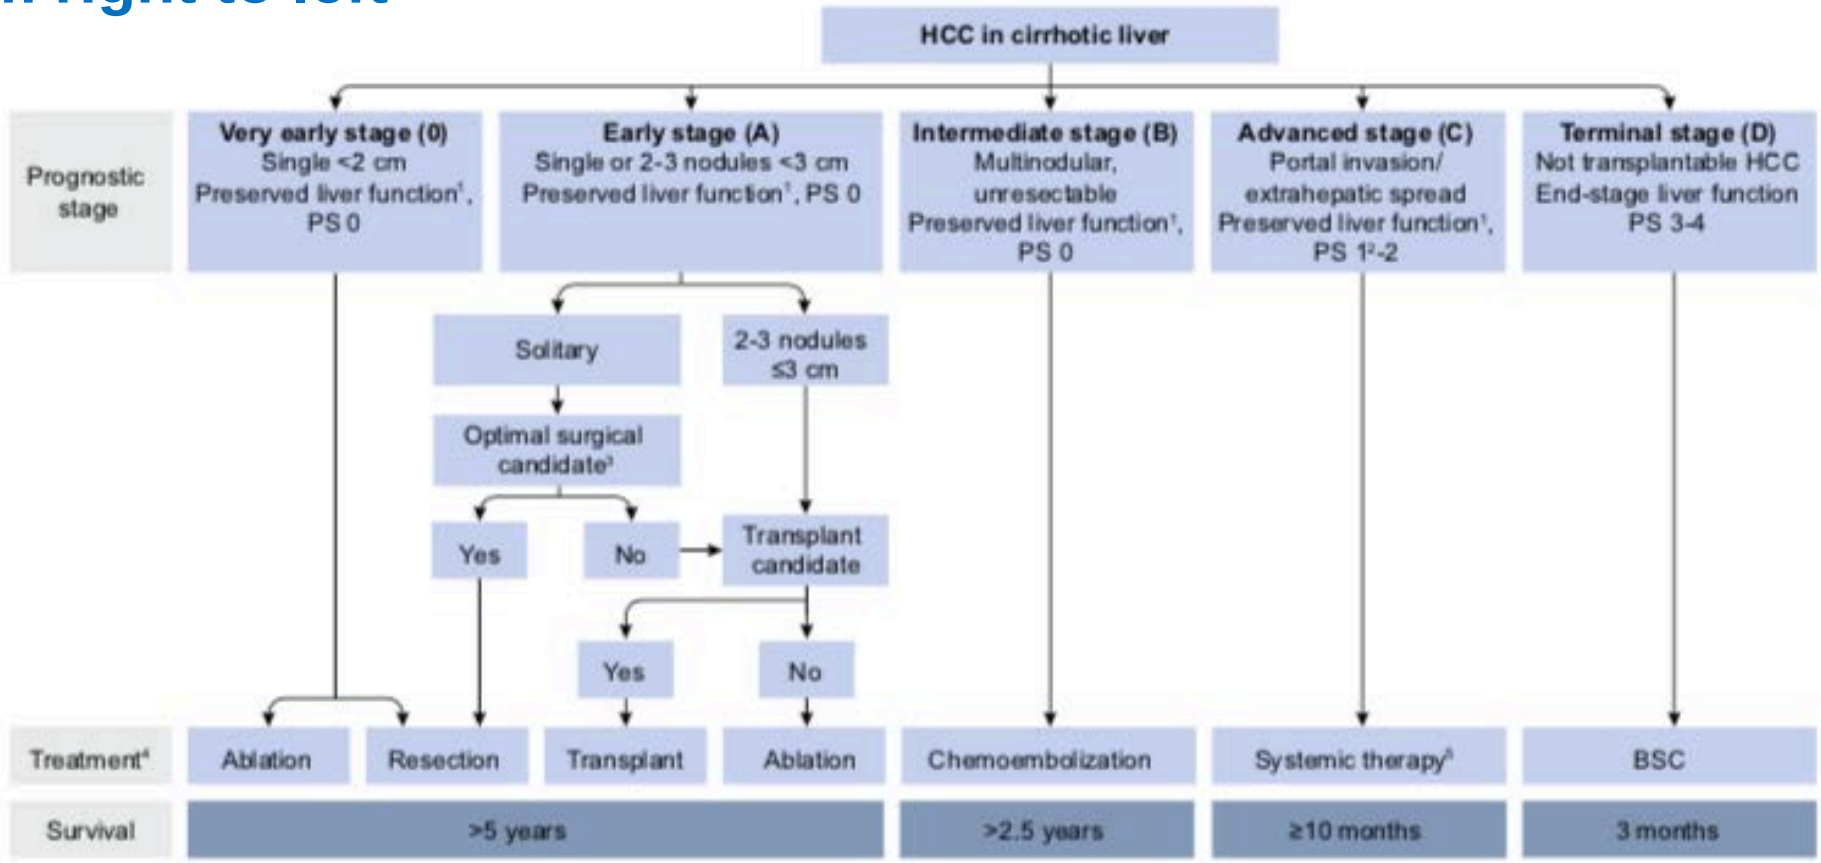

Fig. 3. Modified BCLC staging system and treatment strategy. [1]"**Preserved liver function**" refers to Child-Pugh A without any ascites, considered conditions to obtain optimal outcomes. This prerequisite applies to all treatment options apart from transplantation, that is instead addressed primarily to patients with decompensated or end-stage liver function. [2]**PS 1** refers to tumour induced (as per physician opinion) modification of performance capacity. [3]**Optimal surgical candidacy** is based on a multiparametric evaluation including compensated Child-Pugh class A liver function with MELD score <10, to be matched with grade of portal hypertension, acceptable amount of remaining parenchyma and possibility to adopt a laparoscopic/minimally invasive approach. The combination of the previous factors should lead to an expected perioperative mortality <3% and morbidity <20% including a postsurgical severe liver failure incidence <5%. [4]The **stage migration strategy** is a therapeutic choice by which a treatment theoretically recommended for a different stage is selected as best 1st line treatment option. Usually it is applied with a left to right direction in the scheme (*i.e.* offering the effective treatment option recommended for the subsequent more advanced tumour stage rather than that forecasted for that specific stage). This occurs when patients are not suitable for their first line therapy. However, in highly selected patients, with parameters close to the thresholds defining the previous stage, a right to left migration strategy (*i.e.* a therapy recommended for earlier stages) could be anyhow the best opportunity, pending multidisciplinary decision. [5]As of 2017 sorafenib has been shown to be effective in first line,

Are guidelines a dogma?

Are guidelines a dogma?

Is a non application a deviation?

Is a non application a deviation?

NO, it is probably personalized medicine
ONLY if focused on the best treatment decision in a setting in which ALL therapeutic options are available/contemplated

EASL HCC Committee, J Hepatology 2018

The role of guidelines

Societal guideline committees play an important role in synthesizing the knowledge base and classifying the strength of evidence for new treatments; their endorsements strongly affect practice. Ultimately, however, physicians at the point of care bear the final responsibility for accurately interpreting clinical trial results and for integrating regulatory and guideline recommendations in order to make the best treatment decisions for each patient in their care.

SJ Pocok and GW Stone NEJM 2016;375:971-979

Clinical Practice Guidelines

Update process

Because of the increasing number of publications, guidelines need to be continually updated to reflect the recent state of evidence. After 2023, these guidelines will expire. Should important changes occur in the meantime, such as newly available interventions, new important evidence or withdrawal of drug licensing, the information contained in the guidelines will be outdated earlier. In these cases, an update issue of the guidelines is needed earlier. EASL (cpg@easloffice.eu) will decide if an earlier initiation of an update is required.
