Prostate Imaging Reporting And Data System

- Division of the prostate in (at least) 16 regions
- Scores from T2WI, DWI e DCE-MRI
- Score assignation to each region:
  - Score 1 = Clinically significant disease is highly unlikely to be present;
  - Score 2 = Clinically significant cancer is unlikely to be present;
  - Score 3 = Clinically significant cancer is equivocal;
  - Score 4 = Clinically significant cancer is likely to be present
  - Score 5 = Clinically significant cancer is highly likely to be present.

Prostate Imaging and Reporting and Data System: Version 2

Considerable effort has gone into "curve typing" (i.e. plotting the kinetics of a lesion as a function of signal vs. time). However, there is great heterogeneity in enhancement characteristics of prostate cancers, and at present there is little evidence in the literature to support the use of specific curve types. Another approach is the use of compartmental pharmacokinetic modeling, which incorporates contrast media concentration rather than raw signal intensity and an arterial input function to calculate time constants for the rate of contrast agent wash-in (K^{trans}) and wash-out (k_{ep}). Commercial software programs are available that produce "maps" of K^{trans} and k_{ep} and may improve lesion conspicuity. Although pharmacodynamic (PD) analysis may provide valuable insights into tumor behavior and biomarker measurements for drug development, the PI-RADS Steering Committee believes there is currently insufficient peer reviewed published data or expert consensus to support routine adoption of this method of analysis for clinical use.

Thus, for PI-RADS v2, a "positive" DCE MRI lesion is one where the enhancement is foca earlier or contemporaneous with enhancement of adjacent normal prostatic tissues, and corresponds to a finding on T2W and/or DWI. In the TZ, BPH nodules frequently enhance early, but they usually exhibit a characteristic benign morphology (round shape, well circumscribed). A "negative" DCE MRI lesion is one that either does not enhance early compared to surrounding prostate or enhances diffusely so that the margins of the enhancing area do not correspond to a finding on T2W and/or DWI.

PI-RADS – Report

Motivo della richiesta: rialzo del PSA.

TECNICA DI STUDIO
Esame eseguito con tecnica multiparametrica con acquisizioni multiplanari T1 e T2 pesate, con sequenze pesate in diffusione e con studio dinamico perfusionale durante infusione e.v. di m.d.c. paramagnetico (Gadovist).

REFERTO RADIOLOGICO
DIMENSIONI
Prostata di dimensioni marcatamente aumentate (diametro longitudinale 77 mm, trasverso 69 mm, antero-posteriore 61 mm), per un volume complessivo di circa 170 cc, con voluminoso adenoma che impronta e solleva il pavimento vescicale del volume di circa 110 cc.
ASPETTI MORFOLOGICI
Zona periferica assottigliata, ad intensità di segnale disomogenea per la presenza di strie ipointense di aspetto flogistico cronico.
Noduli di iperplasia stromale, ghiandolare, calcificazioni e cisti da ritenzione a carico della zona transizionale.
LESIONI
Non sono evidenti lesioni con caratteristiche RM di neoplasia significativa a carico della regione periferica o transizionale (PIRADS score 1/5)
CAPSULA
Conservato il profilo capsulare.
VESCICOLE SEMINALI
Vescicole seminali normodistese, nei limiti per morfologia ed intensità di segnale.
VIE URINARIE
Vescica discretamente distesa, senza evidenti ispessimenti patologici.
LINFONODI PELVICI
Non linfonodi aumentati di dimensioni.
STRUTTURE SCHELETRICHE PELVICHE
Non lesioni a carico delle ossa del bacino.

CONCLUSIONI: non alterazioni focali sospette per neoplasia prostatica significativa secondo i criteri PI-RADS v.2.

PITFALLS

Radiologist, Be Aware: Ten Pitfalls That Confound the Interpretation of Multiparametric Prostate MRI

Andrew B. Rosenkrantz[1]
Samir S. Taneja[2]

OBJECTIVE. In this article, we describe 10 diagnostic challenges that may confound the interpretation of multiparametric prostate MRI for tumor, grouped into three categories on the basis of our experience: normal anatomic structures that may be misinterpreted as suspicious lesions if their normal appearance is not recognized, benign processes that may mimic tumor, and technical issues relating to acquisition and interpretation of diffusion-weighted imaging that may decrease sensitivity for tumor. Strategies for addressing these challenges are suggested.

CONCLUSION. It is important that the radiologist involved in the interpretation of prostate MRI be aware of these pitfalls that will be encountered during routine clinical practice. This awareness can contribute to improved diagnostic performance in MRI interpretation.

the central gland [25, 26]. The central gland in most adult males consists of hypertrophied TZ that compresses the CZ against the surgical capsule [25]. Currently, it is acknowledged that the CZ can be identified separately from the TZ in up to 4/5 of males and the CZ appears as a symmetric band of homogeneously low signal intensity (SI) on T2W MRI and apparent diffusion coefficient (ADC) maps best seen at the prostate base [25], (Fig. 1).

Purpose: We determined whether Gleason pattern 4 architecture impacts tumor visibility on multiparametric magnetic resonance imaging and correlates with final histopathology.

Materials and Methods: A total of 83 tumor foci were identified in 22 radical prostatectomy specimens from patients with a prior negative biopsy who underwent magnetic resonance/ultrasound fusion biopsy followed by radical prostatectomy from January 2015 to July 2016. A genitourinary pathologist rereviewed tumor foci for Gleason architectural subtype. Each prostate imaging reporting and data system category 3 to 5 lesion on multiparametric magnetic resonance imaging was paired with its corresponding pathological tumor focus. Univariable and multivariable analyses were performed to determine predictors of tumor visibility.

Results: Of the 83 tumor foci identified 26 (31%) were visible on multiparametric magnetic resonance imaging, 33 (40%) were Gleason score 3+3 and 50 (60%) were Gleason score 3+4 or greater. Among tumor foci containing Gleason pattern 4, increasing tumor size and noncribriform predominant architecture were the only independent predictors of tumor detection on multivariable analysis ($p = 0.002$ and $p = 0.011$, respectively). For tumor foci containing Gleason pattern 4, 0.5 cm or greater, multiparametric magnetic resonance imaging detected 10 of 13 (77%), 5 of 14 (36%) and 9 of 10 (90%) for poorly formed, cribriform and fused architecture, respectively ($p = 0.01$). The size threshold for the detection of cribriform tumors was higher than that of other architectural patterns. Furthermore, cribriform pattern was identified more frequently on systematic biopsy than on targeted biopsy.

Conclusions: Reduced visibility of cribriform pattern on multiparametric magnetic resonance imaging has significant ramifications for prostate cancer detection, surveillance and focal therapy.

ABSTRACT

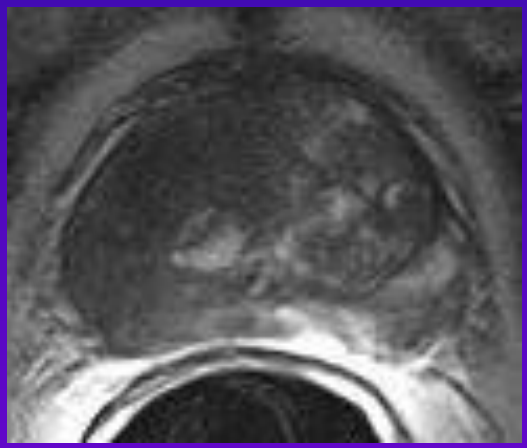
Purpose: To evaluate the accuracy of a 3D-endorectal 1 mm-thick slices MRI acquisition for local staging of low, intermediate and high D'Amico risk prostate cancer (PCa).
Materials and methods: 178 consecutive patients underwent a multiparametric MRI protocol prior to radical prostatectomy (RP). T2W images were acquired with the 3D sampling perfection with application optimized contrasts using different flip angle evolutions (SPACE) sequence (5 mn acquisition time). Direct and indirect MRI signs of extracapsular extension (ECE) were evaluated to predict the pT stage. The likelihood of SVI (seminal vesicle invasion) was also assessed.
Results: Histology showed ECE and SVI in 38 (21%) and 12 (7%) cases, respectively. MRI sensitivity and specificity to detect ECE were 55 and 96% if direct signs of ECE were used and 84 and 89% ($p < 0.05$), if both direct and indirect signs were combined. D'Amico criteria did not influence MRI performance. Sensitivity and specificity for SVI detection were 83% and 99%.
Conclusions: 3D data sets acquired with the SPACE sequence provides a high accuracy for local staging of prostate cancer. The use of indirect signs of ECE may be recommended in low D'Amico risk tumors to optimise patient selection for active surveillance or focal therapy.

- conservative reporting:

- 55% sensitivity
- 96% specificity

- aggressive reporting:

- 84% sensitivity
- 89% specificity



Slight capsular irregularity
Slight capsular undulation

MR CRITERIA FOR DETECTING SV

Seminal vesicle (SV) invasion is an important marker of progression

On T2w images:

- Contiguous low-signal intensity tumour extension from base to SV
- Focal low-signal intensity within the SV disruption
- Loss of the normal structure of SV
- Non visualisation or enlargement of the ejaculatory ducts
- Obliteration of seminal vesicle angle
- Decreased conspicuity of SV

Objectives: The aim of this study is to develop a nomogram of clinical utility based on apparent diffusion coefficient (ADC) from diffusion-weighted imaging to predict extracapsular extension (ECE), and to validate externally its clinical utility.

Materials and methods: A total of 101 men (70 for the creation and 31 for external validation of the nomogram) underwent 1.5T multiparametric magnetic resonance imaging followed by radical prostatectomy at 2 different institutions. ADC values were assessed for normal and pathological tissue. Clinical and pathological variables were investigated by univariate and multivariate logistic regression analyses on 70 patients and logistic regression coefficients were used to develop our nomogram. Receiver operating characteristic curve analysis was performed to determine the optimal ADC cut off for ECE. The nomogram was then externally validated on 31 patients at another institution.

Results: At univariate analysis, the following variables were associated with ECE: pathological ADC and Gleason at biopsy ($P < 0.001$) along with tumor volume and ECE at imaging ($P = 0.003$). At multivariate analysis, pathological ADC ($P = 0.027$), tumor volume ($P = 0.011$), and biopsy Gleason ($P = 0.040$) maintained their independent predictor status and were included in our nomogram together with normal ADC and ECE at imaging. Our nomogram showed a significant higher sensitivity (88%) than T2-weighted imaging (54%; $P = 0.010$). External validation resulted in an overall accuracy of 81%.

Conclusions: ADC represents a potential imaging biomarker to predict side-specific ECE in patients with prostate cancer. Our nomogram could improve the current diagnostic pathway and possibly the therapeutic approach for this disease.

mpMRI– PIRADS 2.0

Table 1 – Management priorities and proposed MRDB strategies according to mpMRI findings from PI-RADS–compliant protocols

Clinical group	Management priority	MRDB strategy	PI-RADS assessment category		
			PI-RADS 1–2	PI-RADS 3	PI-RADS 4–5
Biopsy-naïve	Minimize overdiagnosis and detect csPCa equally	Recommend [e]	TRUS biopsy if high risk [a]	TRUS biopsy ± MRDB	MRDB target + penumbra
		Option	Lower risk clinically, no immediate biopsy; primary care FU	No biopsy if not high risk [a,d]; urologic FU	MRDB target + TRUS
Prior negative TRUS/low-volume GS 3 + 3 (AS)	Do not miss csPCa	Recommend	No biopsy for lower risk; urologic FU [b]	TRUS biopsy ± MRDB	MRDB target + TRUS [c]
		Option	SBx or TPMB if high risk [a,b,c]	SBx/TPMB	MRDB target + penumbra MRDB target + SBx/TPMB [f]
Negative prior MRDB; no TRUS but at high risk [a]	Do not miss csPCa	Recommend	TRUS/SBx/TPMB according to local rules	TRUS biopsy ± MRDB	MRDB target + penumbra MRDB target + penumbra + TRUS MRDB target + penumbra + SBx
		Option	No biopsy; urologic FU	SBx/TPMB	

MRDB = magnetic resonance–directed biopsy; mpMRI = multiparametric magnetic resonance imaging; PI-RADS = Prostate Imaging-Data and Reporting System; AS = active surveillance; csPCa = clinically significant prostate cancer (various definitions); TRUS = transrectal ultrasound systematic 10–12-core biopsy according to international standards; site specific MR-directed biopsy using US/MRI fusion technique or in-bore technique; SBx = saturation biopsy using transrectal or transperineal sampling (eg, Ginsburg approach); TPMB = transperineal mapping biopsy using 5-mm sampling; FU = follow-up.

[a] High risk according to clinical suspicion, family history, prior biopsy result (if applicable), 4K/PHI/PCA3/FH/PSAD risk calculator scores alone or in combination.
